Increased expression of CD30 is associated with a variety of hematologic malignancies, including Hodgkin disease (HD) and anaplastic large cell lymphoma (ALCL). The anti-CD30 monoclonal antibody SGN-30 induces direct antitumor activity by promoting growth arrest and DNA fragmentation of CD30+ tumor cells. In this study, we investigated the contributions of Fc-mediated effector cell functions to SGN-30 activity. We determined that antibody-dependent cellular phagocytosis, mediated by macrophages, to contribute significantly to antitumor activity in vitro. To delineate the identity of the host effector cells involved in mediating antitumor activity in vivo, we studied the effects of effector cell ablation in a disseminated model of HD (L540cy). Depletion of macrophages markedly reduced efficacy of SGN-30, demonstrating that macrophages contribute significantly to SGN-30 efficacy in this model. These findings may have implications for patient stratification or combination treatment strategies in clinical trials conducted with SGN-30 in HD and ALCL.

Introduction

Increased expression of CD30 was observed on Reed-Sternberg cells in Hodgkin disease (HD),1 on neoplastic cells in ALCL, and on a subset of non-Hodgkin lymphomas (NHLs).2 Expression of CD30 on normal cells is restricted to activated T and B cells, because CD30 is not expressed by resting lymphocytes. Such highly restricted expression of CD30 to activated lymphocytes and neoplastic tumor cells led to the investigation of this cell surface antigen as a target for immunotherapy in hematologic malignancies.3 Previous reports demonstrated that SGN-30, a therapeutic antibody binding to CD30, elicits direct effects on tumor cell intrinsic signaling by promoting growth arrest and DNA fragmentation of CD30+ tumors, including HD and anaplastic large cell lymphoma (ALCL), ultimately resulting in cell death.4,5 However, it remained unknown whether SGN-30 engages Fc-mediated effector cell activities. In this report, we demonstrate that macrophages contribute significantly to the anti-tumor activity of SGN-30 in vitro by inducing cellular cytotoxicity via ADCP. In vivo, depletion of macrophages reduced survival of tumor bearing mice treated with SGN-30. In contrast, ablation of natural killer (NK) cells did not significantly affect efficacy in this model. Combined, these data suggest that the interaction between SGN-30 and host macrophages contributes significantly to the mechanisms by which SGN-30 interferes with tumor growth. The newly defined role of macrophages in mediating antitumor activity of SGN-30 identified here may be relevant for the clinical activity of SGN-30, which is currently being developed for HD and ALCL.

Materials and methods

Cells and reagents

CD30+ HD lines: L540cy was provided by Dr Phil Thorpe (University of Texas, Southwestern Medical School, Dallas, TX), and HDLM-2 was obtained from the Deutsche Sammlung von Mikroorganismen und Zellkulturen (Braunschweig, Germany). The CD30- lymphoblast B-cell line WIL2-S and CD30- acute promyelocytic leukemia line HL60 were obtained from the American Type Culture Collection (Manassas, VA). Cells were grown in RPMI [Roswell Park Memorial Institute] 1640 medium (Invitrogen, Carlsbad, CA) supplemented with 10% fetal bovine serum. For in vivo depletion studies, rabbit anti-asialo-GM-1 antibody was obtained from Wako Pure Chemical Industries (Richmond, VA), and rat anti-mouse-Gr-1 antibody was obtained from BD Biosciences (San Jose, CA). Liposome-encapsulated clodronate (CEL) was prepared as described previously.6 Clodronate was a gift of Roche Diagnostics (Mannheim, Germany). SGN-30 was engineered at Seattle Genetics, Inc (Seattle, WA)4 and does not cross-react with rodent CD30.

Antibody-dependent cellular phagocytosis assay

This assay was performed as described previously.7 In brief, once CD30+ target cells were labeled, they were precoated with SGN-30 and then incubated with monocyte-derived macrophages. The macrophages represent the adherent cell components of peripheral blood mononuclear cells (PBMCs) cultured for 10 to 15 days in X-VIVO 15 medium (Lonza BioScience, Walkersville, MD) containing 500 U/mL recombinant human granulocyte macrophage–colony-stimulating factor (PeproTech, Rocky Hill, NJ). Monocytes harvested from these cultures were CD3/CD19-negative and expressed CD14, CD11b, CD16, CD32, and CD64 as determined by flow cytometry or by fluorescence microscopy (Zeiss...
Results and discussion

In this report, we investigated the ability of SGN-30 to engage Fc-mediated effector cell functions in vitro and in vivo. When tested in an antibody-dependent cellular phagocytosis (ADCP) assay, as described previously, SGN-30 induced ADCP against a panel of cell lines including L540cy, HDLM-2, and WIL2-S (Figure 1A,B). As expected, ADCP activity was not observed in the presence of an F(ab')2 fragment of SGN-30 lacking the Fc domain or when a CD30-negative tumor cell line (HL-60) was tested. These findings demonstrate that antitumor activity of SGN-35 was antigen-specific, and that Fc-Fc receptor interactions were necessary for phagocytic uptake of antibody labeled target cells (Figure 1C). The degree of ADCP induced by SGN-30 was comparable with the levels obtained for similar human IgG1 subtype antibodies, targeting cell surface antigens expressed on hematologic tumor cells, including an anti-CD70 antibody. SGN-30 was further tested for its ability to induce cell lysis of CD30+ tumor cells via complement fixation, a process termed complement-dependent cytotoxicity (CDC) and/or via antibody-dependent cellular cytotoxicity (ADCC), mediated by NK cells. For the determination of ADCC, an assay described previously using PBMCs as a source for NK cells was used. In neither assay, we were able to detect significant levels of CDC or ADCC by SGN-30 when tested on a large variety of CD30+ cell lines (data not shown). These findings support the notion that therapeutic antibodies can vary in their potency to engage effector cells, depending on their IgG isotypes and other, less well-characterized characteristics, including antigen binding.
Having demonstrated that SGN-30 induces tumor cell killing via ADCP in vitro, we sought to define the nature of the FcγR-expressing cells that are responsible for SGN-30 targeted cell clearance in vivo. For this purpose, control or SGN-30 treated mice were depleted of NK cells or macrophages as described in “Xenograft models.” As shown in Figure 2, depletion of either NK cells or macrophages in control mice did not significantly affect survival of mice implanted with L540cy tumors (Figure 2A,B). In SGN-30–treated mice, macrophage depletion reduced survival of mice significantly, resulting in a median survival of 81 days compared with a 90% survival at 143 days in the control, non–macrophage-depleted group (Figure 2B). However, despite the profound level of macrophage depletion in most organs achieved in our experiments (data not shown), SGN-30–treated mice survived significantly longer compared with control, untreated mice. These observations are consistent with our previous observations, suggesting that SGN-30 can induce direct tumor cell killing in the absence of effector cells via direct effects on tumor cell signaling, resulting in apoptosis.4

As demonstrated here, Fc-dependent effector-cell functions contribute significantly to the antitumor activity of SGN-30 when tested in a preclinical model of HD. Additional evidence for ADCP contributing to the effects of some therapeutic monoclonal antibodies targeting cell surface markers on hematopoietic cells was provided by other reports.5,10 Even though the role of macrophages in tumor progression is controversial,11 it is tempting to speculate that therapeutic strategies aimed at enhancing host immune cell functions targeting cell surface markers on hematopoietic cells may improve anti-tumor activity. Observation, suggesting that SGN-30 can induce direct tumor cell killing in the absence of effector cells via direct effects on tumor cell signaling, resulting in apoptosis.4

Response to SGN-30 treatment in patients may be less affected by the Fcγ polymorphism if efficacy is predominantly mediated by cells of macrophages/monocyte origin. In contrast, the naturally occurring sequence polymorphisms in the Fcγ receptor IIIa (FcγRIIIA;158V/F) is shown to correlate with therapeutic efficacy of rituximab in clinical trials in NHL,12,13 supposedly by affecting ADCC activity mediated by NK cells.14-16 It is noteworthy that the efficacy of the same therapeutic antibody may not correlate with FcγRIIIA polymorphism in CLL trials, indicating that a different mechanism of action may be operative in different indications.17,18 Macrophages express all 3 subtypes (FcγRIIIA/CD16, FcγRIIA/CD32 and FcγRI/CD64) and FcγRI is involved in ADCP activity, whereas NK cells, which are predominantly involved in ADCC activities, express exclusively FcγRIIa.14,16 For FcγRI, no sequence polymorphisms were reported so far. Based on these observations, it is plausible that ADCP may not be affected by the sequence polymorphisms within the FcγRIIIA alleles. These findings may have implications for patient stratification or combination treatment strategies in clinical trials conducted with SGN-30 in HD and ALCL.
