ADAMTS13 is a multidomain protease that limits platelet thrombogenesis through the cleavage of von Willebrand factor (VWF). We previously identified 2 types of mouse Adamts13 gene: the 129/Sv-strain Adamts13 gene encodes the long-form ADAMTS13 having the same domains as human ADAMTS13, whereas the C57BL/6-strain Adamts13 gene encodes the short-form ADAMTS13 lacking the distal C-terminal domains. To assess the physiologic significance of the distal C-terminal domains of ADAMTS13, we generated and analyzed 129/Sv-genetic background congenic mice (Adamts13+/-). That carry the short-form ADAMTS13. Similar to wild-type 129/Sv mice (Adamts13L/L), Adamts13+/- did not have ultralarge VWF multimers in plasma, in contrast to 129/Sv-genetic background ADAMTS13-deficient mice (Adamts13S/S). However, in vitro thrombogenesis under flow at a shear rate of 5,000 s⁻¹ was accelerated in Adamts13+/- compared with Adamts13L/L. Both in vivo thrombus formation in ferric chloride-injured arterioles and thrombocytopenia induced by collagen plus epinephrine challenge were more dramatic in Adamts13S/S than in Adamts13L/L but less than in Adamts13+/-. These results suggested that the C-terminally truncated ADAMTS13 exhibited decreased activity in the cleavage of VWF under high shear rate. Role of the C-terminal domains may become increasingly important under prothrombotic conditions. (Blood. 2009;113:5323-5329)
In the present study, through using the spontaneous IAP insertion in mouse Adats13 gene, we generated a congenic mouse model that had the distal C-terminally truncated ADAMTS13 on 129/Sv genetic background. While comparing with wild-type 129/Sv mice having full-length ADAMTS13 and ADAMTS13-deficient mice on the same genetic background, we analyzed platelet thrombus formation in the congenic mice to define physiologic significance of the distal C-terminal domains in ADAMTS13 functions. Our results indicate that the distal C-terminal domains of ADAMTS13 contribute to the processing of VWF multimers in vivo, and that the importance of these domains becomes obvious after suffering thrombogenic stimuli.

**Methods**

**Animals**

The 129/Sv mice were purchased from Clea Japan (Tokyo, Japan). C57BL/6 mice were purchased from Japan SLC (Hamamatsu, Japan). ADAMTS13-deficient mice on the 129/Sv genetic background were described previously. ADAMTS13-congenic mice were developed by introgressing the C57BL/6-Adams13 gene onto the 129/Sv genetic background, as follows. C57BL/6 mice were backcrossed to 129/Sv mice for 10 generations while retaining the C57BL/6-Adams13 gene. In the resulting N10 heterozygous mice, autosomal chromosomes were theoretically 99.9% identical to those of the 129/Sv strain and sex chromosomes were derived exclusively from the 129/Sv strain. The N10 heterozygous mice were interbred to produce homozygous mice. The Adats13-genotype was determined by polymerase chain reaction (PCR) with HotStarTag DNA polymerase (QIAGEN, Hilden, Germany). The amplification was carried out using primers: the intron 23-specific forward primer, 5'-ACCTCTCCAAGTGTTTGGGATGCTA-3', the IAP-specific reverse primer, 5'-TCACGGCCTACTTTGTGGGTGCAAAGT-3', and the primer downstream of the IAP target site, 5'-GGCCAGAGGCGCCATTAGATCACTCT-3'. For the experiments, all animals were matched for age and sex. All animal procedures were approved by the Animal Care and Use Committees of the National Cardiovascular Center Research Institute and Immune Disease Institute.

**Northern blot analysis**

Total RNA was extracted from liver using ISOGEN reagent (Nippon Gene, Tokyo, Japan) and poly(A)^+ RNA was purified using PolyATtract mRNA Isolation Systems (Promega, Madison, WI). The alkaline phosphatase-labeled probe was synthesized from mouse Adams13 cDNA (1.3 kb) using AlkPhos Direct labeling module (GE Healthcare, Little Chalfont, United Kingdom). Poly(A)^+ RNA was separated on a 1% agarose gel containing 2% formaldehyde and transferred to a nylon membrane. The probe was hybridized to the blot and detected using CDP-Star detection reagent (GE Healthcare).

**Blood sampling**

Blood was collected from the retro-orbital plexus into tubes containing a 0.1 volume of 3.8% sodium citrate. Blood cell counts and hematocrit were determined using an automatic cell counter (KX-21NV; Sysmex, Kobe, Japan). Plasma was prepared from blood by centrifugation at 800g for 15 minutes.

**Determination of plasma ADAMTS13 activity**

Plasma ADAMTS13 activity was measured using GST-mVWF73-H, a recombinant mouse VWF73 peptide flanked by N-terminal glutathione S-transferase (GST) and C-terminal His6 tags, as described previously. In brief, GST-mVWF73-H (500 ng) was incubated with 0.8 µL plasma in 40 µL reaction buffer (10 mM N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid, 150 mM NaCl, 5 mM CaCl2, and 0.005% Tween 20, pH 7.4) at 37°C for 1 hour. The reaction was stopped by adding 10 µL sodium dodecyl sulfate (SDS) sample buffer (50 mM tris(hydroxymethyl)aminomethane-HCl, 10 mM EDTA, 10% SDS, 250 mM dithiothreitol, 30% glycerol, and 0.1% bromphenol blue, pH 6.8). The samples were subjected to SDS-polyacrylamide gel electrophoresis and Western blot using a rabbit anti-GST antibody (Invitrogen, Carlsbad, CA) and a peroxidase-labeled anti-rabbit IgG antibody (KPL, Gaithersburg, MD). Activity was also determined using a fluorogenic human VWF73 peptide of FRETS-VWF73 (Peptide Institute, Minoh, Japan). Plasma ADAMTS13 activity was measured using GST-mVWF73-H, a D-terminally truncated ADAMTS3 on 129/Sv genetic background. While comparing with wild-type 129/Sv mice having full-length ADAMTS13 and ADAMTS13-deficient mice on the same genetic background, we analyzed platelet thrombus formation in the congenic mice to define physiologic significance of the distal C-terminal domains in ADAMTS13 functions. Our results indicate that the distal C-terminal domains of ADAMTS13 contribute to the processing of VWF multimers in vivo, and that the importance of these domains becomes obvious after suffering thrombogenic stimuli.

**VWF multimer analysis**

Plasma VWF multimer patterns were analyzed as described previously. Plasma samples in SDS sample buffer were electrophoresed on a 1% agarose gel (Agarose IEF; GE Healthcare) at a constant current of 15 mA at 4°C. After transfer to a nitrocellulose membrane, the membrane was incubated in peroxidase-conjugated rabbit anti-human VWF (1:500; Dako, Glostrup, Denmark) in 5% skim milk to detect VWF multimers. Bound antibody was detected with Western Lightening Chemiluminescence Reagent Plus (PerkinElmer, Waltham, MA) on an image analyzer (LAS-3000; Fujifilm, Tokyo, Japan). The chemiluminescent intensities of each lane were scanned using Image Gauge software (version 4.2.2; Fujifilm); the relative intensity profiles were shown.

**Parallel plate flow chamber assay**

Platelet thrombus formation in flowing blood on immobilized collagen was analyzed using a parallel plate flow chamber as described previously. Acid-insoluble type I collagen–coated glass coverslips were placed in a flow chamber. The chamber was mounted on a fluorescence microscope (Axiovert 200M; Carl Zeiss, Oberkochen, Germany) equipped with a CCD camera system (DXC-390; Sony, Tokyo, Japan). Blood was collected into tubes containing argatroban (240 µM; Mitsubishi Chemical, Tokyo, Japan). The fluorescent dye mepacrine (10 µM; Sigma-Aldrich, St Louis, MO) was added to the blood. Whole blood samples were aspirated through the chamber and across the collagen-coated coverslip at a constant wall shear rate. To analyze the cumulative thrombus volume, image sets at 1.0-µm z-axis intervals within a defined area (156.4 µm × 119.6 µm) were captured using MetaMorph software (version 6.1.4; Universal Imaging, West Chester, PA). After blind deconvolution of image sets processed by AutoDeblur software package (version 8.0.2; AutoQuant Imaging, Troy, NY), 3D volumetric measurements of thrombi were accomplished using Voxel3D software (version 3.0; Varetek, Fairfield, IA).

**Intravital microscopy**

Intravital microscopy was performed as described previously. Platelets were isolated from platelet-rich plasma and fluorescently labeled with calcine AM (2.5 µg/mL; Invitrogen). Recipient mice were anesthetized and labeled platelets were infused through retro-orbital plexus. The mesentery was gently exteriorized through a midline abdominal incision and arterioles of 100- to 150-µm diameters were visualized with a fluorescence microscope and a CCD camera system. The shear rate was calculated using an optical Doppler velocimeter as described. Filter paper saturated with 10% ferric chloride was applied for 5 minutes on an arteriole by topical application. Thrombus formation in the arteriole was monitored for 40 minutes after injury or until complete occlusion occurred and lasted for more than 30 seconds. The following 2 parameters were evaluated: the time to first thrombus formation, defined as the time required for formation of a thrombus larger than 30 µm, and occlusion time, defined as the time required for cessation of blood flow for at least 30 seconds.

**Collagen plus epinephrine–induced thrombosis model**

A mixture of 600 ng/g collagen (Nycoderm, Roskilde, Denmark) and 60 ng/g epinephrine (Sigma-Aldrich) was infused into tail vein of mice.
Blood was collected 5 minutes after the infusion and platelet counts were determined.

**Statistical analysis**

Statistical significance was assessed by the one-way analysis of variance followed by the Bonferroni multiple comparison tests. Differences were considered to be significant at \( P < 0.05 \).

**Results**

**Generation of \( \text{Adams13}^{S/S} \) mice**

To address the functional implication of the distal C-terminal domains of ADAMTS13 in vivo, we generated and characterized a congenic mouse model that has the C-terminally truncated form of ADAMTS13 on 129/Sv genetic background (Figure 1A). We confirmed the presence of IAP insertion in the \( \text{Adams13} \) gene of the congenic (\( \text{Adams13}^{S/S} \)) mice by PCR (data not shown) and detected an IAP chimeric transcript (~3.5 kb) by Northern blotting of RNA from liver (Figure 1B), primary site of synthesis.\(^{1} \) An IAP-free ADAMTS13 mRNA (~5 kb) was detected in wild-type 129/Sv (\( \text{Adams13}^{L/L} \)) mice and no ADAMTS13 mRNA was detected in ADAMTS13-deficient (\( \text{Adams13}^{1/-} \)) mice on 129/Sv genetic background (Figure 1B). \( \text{Adams13}^{S/S} \) mouse exhibited higher cleaving activity for both GST-mVWF73-H and FRETS-VWF73 than \( \text{Adams13}^{L/L} \) mouse plasma, whereas the activity in \( \text{Adams13}^{1/-} \) mouse plasma was below detection limits (Figure 1C, D). Therefore, the distal C-terminal domains of ADAMTS13 are not necessary for the cleavage of the VWF73-based peptide substrate as observed previously.\(^{2,3} \) Platelet counts were not different among the genotypes (\( \text{Adams13}^{L/L} \), 744 ± 180 × 10⁹/L; \( \text{Adams13}^{S/S} \), 693 ± 44 × 10⁹/L; \( \text{Adams13}^{1/-} \), 672 ± 39 × 10⁹/L; mean ± SD, \( n = 8 \)). Both \( \text{Adams13}^{S/S} \) mice and \( \text{Adams13}^{1/-} \) mice were viable and showed no TTP-like symptoms throughout the study.

**\( \text{Adams13}^{S/S} \) mice have normal VWF multimers**

As previously reported,\(^{3} \) UL-VWF multimers persisted in plasma of \( \text{Adams13}^{1/-} \) mice on 129/Sv-genetic background (Figure 2). Thus, ADAMTS13 activity is important for the size regulation of VWF multimers in mice at least on this genetic background. However, the VWF multimer patterns in \( \text{Adams13}^{S/S} \) mice were indistinguishable from those in \( \text{Adams13}^{L/L} \) mice (Figure 2). These results suggest that the distal C-terminally truncated form of mouse ADAMTS13 exhibits VWF-cleaving activity sufficient for maintenance of normal size distribution of plasma VWF multimers under steady state in vivo.

**In vitro thrombogenesis is increased in \( \text{Adams13}^{S/S} \) mice only at a high shear rate**

When whole blood was perfused over a collagen-coated surface in a parallel plate flow chamber at a shear rate of 1000 s⁻¹, platelet thrombus formation was significantly promoted in \( \text{Adams13}^{1/-} \) mice (Figure 3A) compared with \( \text{Adams13}^{L/L} \) mice, consistent with the presence of UL-VWF multimers in plasma of \( \text{Adams13}^{1/-} \) mice. However, whole blood thrombus formation at 1000 s⁻¹ was not significantly different between \( \text{Adams13}^{S/S} \) mice and \( \text{Adams13}^{L/L} \) mice (Figure 3A), indicating that the distal C-terminally truncated form of mouse ADAMTS13 does not completely lose the activity.

As fluid shear rate increases progressively, the interaction between VWF and platelet GPIbα becomes more important in platelet thrombus formation.\(^{24} \) It has been reported that thrombus formation in mouse blood on collagen surface is completely dependent on the VWF-GPIbα interaction above a threshold shear rate between 2000 s⁻¹ and 5000 s⁻¹.\(^{24} \) In addition, ADAMTS13 cleaves VWF and down-regulates thrombus formation in shear rate–dependent manner.\(^{28} \) Based on these observations, we further examined thrombus formation at a higher shear rate of 5000 s⁻¹. As expected, thrombus formation in \( \text{Adams13}^{1/-} \) mice was significantly elevated compared with \( \text{Adams13}^{L/L} \) mice at 5000 s⁻¹ (Figure 3B). In addition, we found accelerated thrombus formation in \( \text{Adams13}^{S/S} \) mice compared with \( \text{Adams13}^{L/L} \) mice at this higher shear rate (Figure 3B). These results suggest that the distal C-terminally truncated form of mouse ADAMTS13 has reduced
To elucidate the consequences of the lack of the distal C-terminal domains of ADAMTS13 on systemic thrombosis, we performed collagen plus epinephrine infusion model experiments. In this model, widespread intravascular thrombosis was induced by intravenous infusion of collagen fibrils in combination with epinephrine, and the incorporation of platelets into thrombi was monitored by the reduction in circulating platelet counts. Consistent with our previous observation, platelet counts after the infusion were significantly lower in \( \text{Adamts13}^{-/-} \) mice (time to first thrombus = 7.8 ± 1.3 minutes, occlusion time = 15.3 ± 3.6 minutes), indicating that ADAMTS13 contributes to down-regulation of thrombogenesis at the site of arteriolar injury in 129/Sv mice. However, the initial thrombi grew rapidly to occlusive size in \( \text{Adamts13}^{-/-} \) mice and occlusion time was significantly shorter in \( \text{Adamts13}^{-/-} \) mice compared with \( \text{Adamts13} \) mice (Figure 4B). These results suggest that the distal C-terminally truncated form of mouse ADAMTS13 is less active in down-regulating thrombus growth in vivo compared with full-length ADAMTS13.

To examine whether the truncation of the distal C-terminal domains in ADAMTS13 affects thrombus formation in vivo, we carried out intravital microscopy experiments in a model of experimental arteriolar thrombosis. In this model, widespread intravascular thrombosis was induced by topical application of ferric chloride on a mesenteric arteriole, which provoked the generation of free radicals leading to the endothelial disruption. The diameter and shear rate of studied arterioles were 118.0 plus or minus 13.1 µm and 1362 plus or minus 219 s\(^{-1}\) (mean ± SD, \( n = 16 \)) for \( \text{Adamts13}^{+/+} \) mice, 122.8 plus or minus 11.1 µm and 1394 plus or minus 136 s\(^{-1}\) (\( n = 16 \)) for \( \text{Adamts13}^{+/S} \) mice, and 115.6 plus or minus 10.8 µm and 1405 plus or minus 225 s\(^{-1}\) (\( n = 12 \)) for \( \text{Adamts13}^{-/-} \) mice and not significantly different among the groups. Both time to first thrombus (Figure 4A) and occlusion time (Figure 4B) after injury in \( \text{Adamts13}^{-/-} \) mice (time to first thrombus = 5.1 ± 1.9 minutes, occlusion time = 9.2 ± 1.6 minutes; mean ± SD) were significantly decreased compared with \( \text{Adamts13}^{+/+} \) mice (time to first thrombus = 7.8 ± 1.3 minutes, occlusion time = 15.3 ± 3.6 minutes), indicating that ADAMTS13 contributes to down-regulation of thrombogenesis at the site of arteriolar injury in 129/Sv mice. In the case of \( \text{Adamts13}^{+/S} \) mice, time to first thrombus after injury (7.6 ± 1.2 minutes) was not different from \( \text{Adamts13}^{+/+} \) mice. However, the initial thrombi grew rapidly to occlusive size in \( \text{Adamts13}^{+/S} \) mice and occlusion time was significantly shorter in \( \text{Adamts13}^{+/S} \) mice (12.5 ± 1.9 minutes) compared with \( \text{Adamts13}^{+/+} \) mice (Figure 4B). These results suggest that the distal C-terminally truncated form of mouse ADAMTS13 is less active in down-regulating thrombus growth in vivo compared with full-length ADAMTS13.

To examine whether the truncation of the distal C-terminal domains in ADAMTS13 affects thrombus formation in vivo, we carried out intravital microscopy experiments in a model of experimental arteriolar thrombosis. In this model, widespread intravascular thrombosis was induced by topical application of ferric chloride on a mesenteric arteriole, which provoked the generation of free radicals leading to the endothelial disruption. However, the initial thrombi grew rapidly to occlusive size in \( \text{Adamts13}^{+/S} \) mice and occlusion time was significantly shorter in \( \text{Adamts13}^{+/S} \) mice (12.5 ± 1.9 minutes) compared with \( \text{Adamts13}^{+/+} \) mice (Figure 4B). These results suggest that the distal C-terminally truncated form of mouse ADAMTS13 is less active in down-regulating thrombus growth in vivo compared with full-length ADAMTS13.
accelerated thrombus growth in 129/Sv-background ADAMTS13-deficient mice. By this approach, we minimized the background effects and defined the significance of the distal C-terminal domains of ADAMTS13 in mice.

Plasma of the congenic mice exhibited higher cleaving activity against GST-mVWF73-H and FRETS-VWF73 compared with plasma of the wild-type mice. We previously observed that the recombinant distal C-terminally truncated mouse ADAMTS13 cleaves GST-mVWF73-H to a similar extent compared with the full-length form. These other group reported that the recombinant distal C-terminally truncated mouse ADAMTS13 is slightly less active in cleaving GST-mVWF73-H than the full-length form. These findings suggest that the distal C-terminally truncated ADAMTS13 in mouse plasma has equivalent or slightly lower specific activity against VWF73-based substrates compared with the full-length ADAMTS13. Thus, the data in the present study imply that the distal C-terminally truncated ADAMTS13 is more abundant than the full-length form in circulating blood in 129/Sv mice. Preferential expression of the distal C-terminally truncated mouse ADAMTS13 has also been found in HeLa cells and HEK 293T cells. Unfortunately, because we have failed to determine the ADAMTS13 antigen levels in mouse plasma, it remains unclear whether the distal C-terminal truncation of ADAMTS13 actually increases plasma levels of the enzyme. Despite the congenic mice having higher in vitro ADAMTS13 activity in plasma, they showed prothrombotic phenotypes, suggesting the importance of the distal C-terminal domains in ADAMTS13 activity in vivo.

We reconfirmed that ADAMTS13 deficiency in 129/Sv mice allowed the accumulation of UL-VWF multimers in plasma (Figure 2), therefore, promising the essential contribution of ADAMTS13 on preventing the accumulation of UL-VWF multimers in 129/Sv mice. Under these situations, lack of the distal C-terminal domains of ADAMTS13 in 129/Sv mice did not increase plasma VWF multimer sizes (Figure 2), showing that the distal C-terminally truncated ADAMTS13 maintained the VWF-cleaving activity in vivo. Although the distal C-terminally truncated form of mouse ADAMTS13 was reported to show considerably lower activity than the full-length form for purified human VWF multimers under in vitro static conditions, our results show that the distal C-terminal truncation of mouse ADAMTS13 allows retention of normal size distribution of plasma VWF multimers in vivo at least under steady state.

In the parallel-plate flow chamber experiments, ADAMTS13 deficiency in 129/Sv mice markedly enhanced thrombogenic responses (Figure 3), indicating that ADAMTS13 is critical for limiting platelet thrombus formation under whole blood flow conditions. In the same experimental conditions, the distal C-terminal truncation of ADAMTS13 in 129/Sv mice did not promote thrombogenesis at 1000 s⁻¹ (Figure 3A) but significantly promoted thrombogenesis at 5000 s⁻¹ (Figure 3B). It is conceivable that the distal C-terminally truncated ADAMTS13 is active but not fully competent to cleave VWF within growing thrombus under flow. Because both the interaction of GPIb-α-VWF and the cleavage of VWF by ADAMTS13 are facilitated by increasing fluid shear rate, the function of the distal C-terminal domains may become vital to down-regulate thrombogenesis under high shear conditions. Actually, similar results were obtained in the in vivo arteriolar injury model experiments (Figure 4). The distal C-terminal truncation of ADAMTS13 in 129/Sv mice did not affect the time to first thrombus formation in the arterioles where fluid shear rates were around 1500 s⁻¹ (Figure 4A). However, when thrombus grew to a larger size, the arteriolar lumen was narrowed, which resulted in increase in shear rates. Then, the distal C-terminal truncation of

(28 ± 8 × 10⁹/μL, mean ± SD) than in Adamt13L/L mice (85 ± 33 × 10⁹/μL), suggesting that ADAMTS13 contributes to inhibition of platelet aggregation in this experimental system (Figure 5). Platelet counts after the infusion in Adamt13S/S mice (56 ± 24 × 10⁹/μL) were significantly higher than in Adamt13L/L mice and lower than in Adamt13S/L mice (Figure 5), whereas platelet counts of untreated mice were not different among the groups (Adamt13L/L, 666 ± 44 × 10⁹/μL; Adamt13S/S, 770 ± 65 × 10⁹/μL; Adamt13L/S, 710 ± 49 × 10⁹/μL, mean ± SD of 4 mice). These findings complement accelerated thrombus growth in Adamt13S/S mice compared with Adamt13S/L mice, indicating that the distal C-terminally truncated form of mouse ADAMTS13 has significantly reduced activity in vivo.

**Discussion**

It is now evident that genetic background is an important phenotypic determinant in mutant mice with hemostatic defects. For instance, mice carrying the factor V Leiden (R504Q) mutation have shown increased perinatal thrombotic mortality on the mixed 129/Sv and C57BL/6J background relative to C57BL/6J background. Similar effects of genetic backgrounds on phenotypes have been observed in other mutants such as the thrombomodulin G404P-mutant mice, the fibrinogen-deficient mice, and the tissue factor–deficient mice. In ADAMTS13-deficient mice, genetic backgrounds have also been shown to significantly affect their thrombotic phenotypes. Thus, phenotypes of ADAMTS13 mutant mice should be compared with control mice on the appropriate and uniform strain background. We have previously demonstrated that ADAMTS13 deficiency in mice results in a prothrombotic state with accumulation of UL-VWF multimers on 129/Sv background. Therefore in this study, we applied a spontaneous mutation in the Adamt13 gene of C57BL/6 mice onto 129/Sv mice by 10-generation backcrossing, and obtained the congenic mice that were expected to have 99.9% 129/Sv genome and primarily expressed the distal C-terminally truncated ADAMTS13. Then, we compared their phenotypes with positive and negative control animals: the wild-type 129/Sv mice and the
ADAMTS13 significantly reduced the occlusion time compared with full-length ADAMTS13 (Figure 4B). Therefore, the distal C-terminal domains are important for ADAMTS13 to sufficiently down-regulate thrombogenesis under high shear rate in vivo as well as in vitro. After the induction of systemic platelet aggregation by challenge with a mixture of collagen and epinephrine, consumptive thrombocytopenia was also enhanced by the distal C-terminal truncation of ADAMTS13 in 129/Sv mice (Figure 5), supporting the idea that the distal C-terminal domains are required for optimal down-regulation of platelet aggregation in vivo. The complete deficiency of ADAMTS13 in 129/Sv significantly accelerated thrombus growth to injured vessel wall and systemic thrombi compared with 129/Sv mice with truncation of the distal C-terminal domains in ADAMTS13 (Figures 4,5). Therefore, we can conclude that the distal C-terminally truncated ADAMTS13 has significantly decreased activity in limiting thrombosis in vivo.

The binding of platelets to VWF is reported to accelerate the cleavage of VWF by ADAMTS13 under static and flow conditions in vitro. It has also been shown that ADAMTS13 can cleave platelet-bound VWF multimers and limit thrombus formation through the cleavage of VWF at the surface of forming thrombi in vitro chamber systems. Therefore, in our experimental settings, ADAMTS13 attenuates thrombus growth, possibly through the cleavage of VWF multimers bound on the surface of platelet-rich thrombi under high shear rate. The distal C-terminal domains may be necessary for ADAMTS13 to efficiently recognize and cleave platelet-bound VWF multimers on a growing thrombus. Conceivably, the distal C-terminal domains may contribute to the interaction with unidentified ADAMTS13-binding cofactors localized on the surface of platelets or subendothelium, and this interaction may be necessary for ADAMTS13 to control VWF-mediated thrombus formation. However, we cannot rule out the possibility that the distal C-terminal domains of ADAMTS13 contribute to the prevention of thrombosis independent from the VWF-cleaving activity of ADAMTS13, nevertheless VWF has been suggested as the only relevant substrate for ADAMTS13 and functions of ADAMTS13 other than its VWF-cleaving activity have yet to be reported.

The distal C-terminally truncated ADAMTS13 is expressed in a lot of mouse strains including the BALB/c, C3H/He, C57BL/6, and DBA/2 strains as substitute for the full-length form. Our present results suggest that thrombogenic response in these strains would be increased, at least partially, by their incomplete ADAMTS13 activity. This should be taken into account when studying genetically modified mice with heterogeneous genetic background.

In summary, our results define the role of the distal C-terminal domains in ADAMTS13 in vivo. Deletion of the C-terminal 2 Tsp1 and 2 CUB domains permits normal size distribution of plasma VWF multimers under steady state, but exacerbates platelet thrombosis after thrombogenic stimulation in mice. Thus, the distal C-terminally truncated ADAMTS13 is not fully active in vivo. These distal C-terminal domains of ADAMTS13 may play a role in the efficient processing of VWF multimers during platelet thrombus growth, and thus their functions may become increasingly important when vascular damage is induced.
