Iron-deficiency anemia from matriptase-2 inactivation is dependent on the presence of functional Bmp6

Hepcidin is the master regulator of iron homeostasis. In the liver, iron-dependent hepcidin activation is regulated through Bmp6 and its membrane receptor hemouvelin (Hjv), whereas, in response to iron deficiency, hepcidin repression seems to be controlled by a pathway involving the serine protease matriptase-2 (encoded by Tmprss6). To determine the relationship between Bmp6 and matriptase-2 pathways, Tmprss6−/− mice (characterized by increased hepcidin levels and anemia) and Bmp6−/− mice (exhibiting severe iron overload because of hepcidin deficiency) were intercrossed. We showed that loss of Bmp6 decreased hepcidin levels; increased hepatic iron; and, importantly, corrected hematologic abnormalities in Tmprss6−/− mice. This finding suggests that elevated hepcidin levels in patients with familial iron-refractory, iron-deficiency anemia are the result of excess signaling through the Bmp6/Hjv pathway.

Introduction

Iron supply in the body is provided both by iron recycling from senescent erythrocytes within the reticuloendothelial system and dietary iron absorption by duodenal enterocytes. The liver-iron regulatory hormone, hepcidin, controls these 2 iron-delivery pathways via its targeted degradation of the cell surface iron exporter, ferroportin. As a consequence, iron availability in the circulation is decreased, leading to hypoferraemia. Neither the lack of hepcidin nor its excess can be compensated for by the body, the results of which ultimately manifest in either iron overload or iron-deficiency anemia, respectively.

Hepcidin gene expression is tightly regulated by body iron status and is dependent on bone morphogenetic protein 6 (Bmp6) and hemouvelin (Hjv). Binding of the iron-regulated Bmp6 ligand to its receptors activates a signaling cascade leading to hepcidin transcription via phosphorylation of son of mother against tumor. The critical role of the Bmp6/Hjv/Smad pathway in iron homeostasis is supported by the loss of hepcidin expression and massive parenchymal iron overload observed in Bmp6−/− and Hjv−/− mice as well as in mice with targeted liver deletion of Smad4.

Recently, the serine protease matriptase-2 (also known as tpmprss6) has been connected to this iron pathway because of its proteolysis of Hjv. Matriptase-2 is a type 2 serine protease that is proteolyzed in the liver (for review). Matriptase-2-deficient mice have very high levels of hepcidin, which lead to inhibition of dietary iron absorption and cause severe iron-deficiency anemia phenotype. Matriptase-2 was thus characterized as a negative regulator of hepcidin gene expression. Accordingly, Du et al demonstrated that overexpression of normal matriptase-2 protein in hepatoma cells suppresses the activation of hepcidin expression. The anemic phenotype of matriptase-2-deficient mice is mirrored in patients with matriptase-2 mutations who present with iron-refractory, iron-deficiency anemia.

The goal of this study was to characterize the in vivo relationship between matriptase-2 and the iron-regulated ligand of Hjv, Bmp6, by analyzing the role of Bmp6 in the setting of anemia in mice deficient for matriptase-2. Toward this purpose, we intercrossed matriptase-2 and Bmp6-deficient mice and compared the iron status of the double-mutant mice with that of wild-type controls or single-mutant mice.

Methods

Tmprss6tm1Otin mice on a mixed 129/Ola × C57BL/6 background were mated to Bmp6tm1Rob mice on an outbred CD1 background. F1 mice, heterozygous for both the Tmprss6tm1Otin (hereafter referred to as Tmprss6+/−) and the Bmp6tm1Rob alleles (referred to as Bmp6+/−) were then intercrossed and the F2 progeny genotyped as previously described. As expected, the 9 possible genotypic combinations were observed among the F2 mice.

Mice were cared for in accordance with the European convention for the protection of laboratory animals. Animals were given free access to tap water and standard laboratory mouse chow diet (A03, iron content 280 mg/kg). Mice used in this study were 8- to 13-week-old females and had a mixed 129/Ola × C57BL/6 × CD1 background.

Hematologic parameters as well as plasma and liver iron were obtained as previously described.

From www.bloodjournal.org by guest on April 10, 2017. For personal use only.
RNA extraction and real-time quantification of the hepcidin and β-actin transcripts were performed as reported by Chung et al.\textsuperscript{18} Standardized genetic nomenclature for mouse hepcidin is \textit{Hamp} and \textit{Atcb} for β-actin.

Student \textit{t} tests were used to compare quantitative traits between mouse groups. \textit{P} values less than .05 were considered as statistically significant.

**Results and discussion**

To investigate the role of Bmp6 in the pathogenesis of iron-refractory, iron-deficiency anemia, we intercrossed matriptase-2 and Bmp6-deficient mice and analyzed iron metabolism in their F2 progeny.

As recently published,\textsuperscript{6,7} liver hepcidin expression was repressed in \textit{Bmp6\textsuperscript{-/-}} mice compared with \textit{Bmp6\textsuperscript{+/+}} controls (Figure 1A). A similar pattern of expression was observed for \textit{Id1} mRNA expression relative to β-actin (Figure 1D). However, their expression of \textit{Tmprss6} was not significantly different from the wild-type controls (data not shown). Furthermore, as shown in Table 1, hematologic parameters of \textit{Bmp6\textsuperscript{-/-}} mice were similar to those of \textit{Bmp6\textsuperscript{+/+}} controls.

Conversely, hepcidin and \textit{Id1} gene expressions were significantly up-regulated in \textit{Tmprss6\textsuperscript{-/-}} mice (Figure 1A-D), and as expected,\textsuperscript{12} these mice had reduced hepatic and plasma iron indices, compared with \textit{Tmprss6\textsuperscript{+/+}} controls (Figure 1B-C). In addition, \textit{Tmprss6\textsuperscript{-/-}} mice were anemic and presented with significantly decreased hemoglobin levels, as well as red blood cell count, hematocrit, and mean corpuscular volume (Table 1). In addition, as previously reported,\textsuperscript{19} they exhibited lower \textit{Bmp6} gene expression than wild-type controls (data not shown).

It is interesting to note that, in double-mutant \textit{Bmp6\textsuperscript{-/-} Tmprss6\textsuperscript{-/-}} mice, hepcidin expression was repressed to the same extent as in \textit{Bmp6\textsuperscript{-/-}} mice (Figure 1A). A similar pattern of expression was observed for \textit{Id1}, although the comparison did not reach statistical significance because of a slightly higher variability of gene expression levels between mice for \textit{Id1} than for hepcidin (Figure 1D). In addition, phosphorylation of Smad1/5/8 appeared similarly decreased in \textit{Bmp6\textsuperscript{-/-} Tmprss6\textsuperscript{+/+}} mice and in \textit{Bmp6\textsuperscript{-/-} Tmprss6\textsuperscript{-/-}} mice, compared with wild-type controls (data not shown), which is concordant with the similar reduction we observed in their levels of hepcidin expression. However, although liver and plasma iron levels were higher in \textit{Bmp6\textsuperscript{-/-} Tmprss6\textsuperscript{-/-}} mice than in \textit{Bmp6\textsuperscript{-/-}} mice, these levels remained significantly lower than in \textit{Bmp6\textsuperscript{-/-}} mice (Figure 1B-C). Lastly, and most importantly, iron-deficiency anemia observed in the \textit{Tmprss6\textsuperscript{-/-}} mice was completely rescued by \textit{Bmp6\textsuperscript{+/-}} deficiency. As shown in Table 1, values of hemoglobin, hematocrit, and mean corpuscular volume observed in \textit{Bmp6\textsuperscript{-/-} Tmprss6\textsuperscript{-/-}} mice were comparable to control values. Furthermore, heterozygous loss of \textit{Bmp6} in \textit{Tmprss6\textsuperscript{-/-}} mice was able to...
partially correct systemic iron homeostasis by decreasing hepcidin gene expression and increasing plasma and liver iron levels (Figure 1).

Although hematologic parameters were found to be normal in mice deficient for both Hjv and matriptase-2, supporting the role of matriptase-2 as a regulator of Hjv expression at the hepatocyte membrane, the role of Bmp6 in this process was not clearly defined. The data obtained in this study indicate that hepcidin overexpression, which results from matriptase-2 inactivation, requires the presence of Bmp6. Indeed, neither the activation of the Hjv/Smad signaling pathway nor the establishment of the anemic phenotype was observed in double knockout mice.

However, in contrast to Hjv−/− Tmprss6−/− mice, which had a phenotype very similar to Hjv−/− mice, we found that loss of matriptase-2 in Bmp6−/− Tmprss6−/− mice attenuates the effects of Bmp6 deficiency on hepatic and plasma iron accumulation. It could be speculated that, because of the lack of matriptase-2, Hjv is stabilized at the hepatocyte plasma membrane and can serve as a coreceptor for ligands other than Bmp6. However, neither hepcidin nor Id1 gene expression were found to be up-regulated in the double-mutant female mice compared with Bmp6−/− mice. Alternatively, matriptase-2 could, in absence of Bmp6, regulate other iron-related proteins or initiate a signaling pathway involved in maintaining hepatic iron balance and/or systemic iron regulation, independently of hepcidin.

In conclusion, the present data further support that Bmp6 is the physiologic ligand of Hjv and demonstrate that the regulation of Hjv expression by matriptase-2 serves to tightly control the signaling pathway induced by Bmp6.
