NK-cell leukemia is a clonal expansion of NK cells. The illness can occur in an aggressive or chronic form. We studied cell lines from human and rat NK-cell leukemias (aggressive NK-cell leukemia) as well as samples from patients with chronic NK-cell leukemia to investigate pathogenic mechanisms. Here we report that Mcl-1 was overexpressed in leukemic NK cells and that knockdown of Mcl-1 induced apoptosis in these leukemic cells. In vitro treatment of human and rat NK leukemia cells with FTY720 led to caspase-dependent apoptosis and decreased Mcl-1 expression in a time- and dose-dependent manner. These biologic effects could be inhibited by blockade of reactive oxygen species generation and the lysosomal degradation pathway. Lipidomic analyses after FTY720 treatment demonstrated elevated levels of sphingosine, which mediated apoptosis of leukemic NK cells in vitro. Importantly, systemic administration of FTY720 induced complete remission in the syngeneic Fischer rat model of NK-cell leukemia. Therapeutic efficacy was associated with decreased expression of Mcl-1 in vivo. These data demonstrate that therapeutic benefit of FTY720 may result from both altered sphingolipid metabolism as well as enhanced degradation of a key component of survival signaling.

(Blood. 2011;118(10):2793-2800)

Introduction

Large granular lymphocyte (LGL) leukemia is a clonal disease representing a spectrum of biologically distinct lymphoproliferative diseases originating either from mature T cells (CD3+ or NK cells (CD3–). Both CD3+ and CD3– LGLs function as cytotoxic lymphocytes. The 2008 World Health classification of mature T- and NK-cell neoplasms continues to distinguish T-cell LGL leukemia (T-LGL leukemia) from aggressive NK-cell leukemia based on their unique molecular and clinical features. Furthermore, a new provisional entity of chronic lymphoproliferative disorder of NK cells (also known as chronic NK-cell lymphocytosis or chronic NK-LGL leukemia) was created to distinguish it from much more aggressive NK-cell leukemia.1 Both aggressive NK-cell leukemia and chronic NK-cell leukemia display CD3–CD56+ immunophenotype.1 Aggressive NK-cell leukemia is a fatal illness which pursues a very malignant clinical course characterized by refractoriness to conventional chemotherapy, and a short median survival time of 2 months.2-4 There are no effective therapies for this disorder and pathogenic mechanisms remain undefined. FTY720 has recently shown preclinical activity in hematologic malignancies. At low nanomolar concentrations, FTY720 becomes phosphorylated in vivo and acts as a potent agonist for sphingosine 1 phosphate receptors. In this capacity, as an immunomodulatory drug, FTY720 was recently approved by the Food and Drug Administration for treatment of multiple sclerosis, based on phase 3 efficacy data.5 In contrast, at high micromolar dosages, FTY720 has shown antitumor activity, inducing apoptosis of leukemic cells through a PP2A-dependent mechanism.6,7 Here we report biologic activity of FTY720 in chronic and aggressive NK-cell leukemia. FTY720 induced apoptosis of leukemic NK cells by degrading Mcl-1 through a lysosomal rather than a proteasomal pathway. Lipidomic experiments demonstrated increased levels of proapoptosis sphingosine in leukemic cells after FTY720 treatment. Previously, we used the Fischer rat NK-cell leukemia model to demonstrate efficacy of nanoliposomal ceramide. Using this animal model, we show here that FTY720 induced complete remission of aggressive NK-cell leukemia.

Methods

Reagents and cell culture

FTY720 was synthesized and supplied in powder form by the Organic Synthesis Core facility in the Penn State Hershey Cancer Institute following methods as previously described.8 GAPDH Ab and cathepsin B Ab were purchased from Cell Signaling Technology Inc. Mcl-1 Ab (S-19) was purchased from Santa Cruz Biotechnology. For Western blotting, 12% precasted Nupage electrophoresis gels were obtained from Invitrogen, and ECL reagent was purchased from Amersham Biosciences Inc. Human NKL cells (kindly provided by Dr Howard Young, National Cancer Institute) were grown in RPMI 1640 medium supplemented with 20% FBS plus 100 IU/mL IL-2. RNK-16 cells (kindly provided by Dr Craig Reynolds, National Cancer Institute) were cultured in RPMI 1640 supplemented with 10% FBS.
Figure 1. FTY720 induces apoptotic cell death in leukemic NK cells in a dose-dependent manner. (A) Human NKL cell line was treated with 5, 10, and 15 μM FTY720 or DMSO for 24 hours, then cells were assayed for apoptosis by flow cytometry. (B) Rat RNK-16 cell line was treated with 2.5, 5, and 10 μM FTY720 or DMSO for 24 hours then cells were assayed for apoptosis by flow cytometry. (C) PBMCs from one acute NK-cell leukemia patient (no. 1) and 3 chronic NK-cell leukemia patients (nos. 2, 3, 4) were treated with 2.5, 5, and 10 μM FTY720 or DMSO for 18 hours, then cells were assayed for apoptosis by flow cytometry. *P<.005, **P<.0005 indicate significant differences of FTY720-treated cells versus DMSO-treated cells (Student t test).

Patient characteristics and preparation of PBMCs

All patients met the clinical criteria of NK-cell leukemia with increased numbers (>80%) of CD3+/CD56+ NK cells in the peripheral blood. Nine patients had chronic NK-cell leukemia while one patient had aggressive NK-cell leukemia. Patients received no treatment at the time of sample acquisition. Peripheral blood specimens from these patients were obtained and informed consents signed for sample collection according to a protocol approved by the Institutional Review Board of Penn State Hershey Cancer Institute. Buffcoats from 8 age- and sex-matched normal donors were also obtained from the blood bank of Milton S. Hershey Medical Center (College of Medicine, Penn State University). PBMCs were isolated by Ficoll-Hypaque gradient separation, as described previously.9 Cell viability was determined by trypan blue exclusion assay with >95% viability in all the samples. NK cells from additional 11 age- and sex-matched healthy donors were isolated by a negative selection process (StemCell Technologies), as described previously.10 The purity of freshly isolated CD3+/CD56+ cells (2 × 10^6/sample in triplicate) in each of the samples was determined by flow cytometric assay by detecting positive staining of the CD56 marker for NK cells. The purity for normal purified NK cells was between 85% and 90%.

In vitro apoptosis and cell viability assay

Apoptosis was determined by 2-color flow cytometry with annexin V (5 μL/sample; BD Pharmingen) and 7-aminoadeninecidin D (7-AAD; 10 μL/sample) staining using 5 × 10^5 cells per sample. The percentage-specific apoptosis was calculated using the following: apoptosis (%) = % annexin V−FITC-positive in assay well. Cell viability was performed using the CellTiter 96 Aqueous One Solution assay kit (Promega).10 The relative viable cell number was determined by reading the plates at 490-nm wavelength in a Synergy HT Multi-Detection microplate reader (Bio-Tek).

Mcl-1 expression: Western blot

Purified NK cells from 5 chronic NK-cell leukemia patients as well as 10 pooled normal NK cells from age- and sex-matched healthy donors were isolated by a negative selection process (StemCell Technologies). RNK-16 cells (5 × 10^5) or patients’ PBMCs (CD3+/CD56+ > 80%) treated with different doses of FTY720 at different times were lysed in buffer containing: 150 mM NaCl, 1% Nonidet P-40, 0.5% deoxycholic acid, 0.1% SDS, 50 mM Tris, and protease inhibitor cocktail (Sigma-Aldrich). Lysate was then used for Western blotting with Mcl-1 Ab.

Mcl-1 shRNA-mediated protein knockdown

The pLKO.1-based lentiviral shRNA targeting human Mcl-1, TRCN0000005517, and pLKO.1-based scrambled control shRNA vector were purchased from Open Biosystems. The plasmids were prepared with the plasmid max kit and transfected in HEK293FT cells (Invitrogen) with the transfection reagent (Invitrogen) to produce lentiviral particles. RNK, a human NK-cell leukemia cell line, was infected with the concentrated lentiviral stocks in the presence of 8 μg/mL polybrene for 24 hours and then changed to RPMI 1640 medium for an additional 48 hours. Protein lysates were collected for Western blot analysis of Mcl-1 expression and apoptosis assays were performed.

Cathepsin B release assay: isolation of cytosol

Lysosomal integrity was assessed by estimation of the amount of cathepsin B translocated to the cytosol during lysosomal stress. Cytosolic extraction was performed using a Subcellular Protein Fractionation Kit (Thermo Scientific). The cytosolic fraction lysate was then used for Western blotting with a cathepsin B Ab.

Confocal studies

To verify cell accumulation of FTY720 into RNK16 cells, cells were plated at 2.0 × 10^4 per well in 8-well chamber slides and allowed to grow overnight. RNK-16 cells were treated with 5 μM FTY720 for 2 hours. Cellular nuclei were counterstained with Hoechst 33258; Lysotracker and MitoTracker Deep Red 633 (Molecular Probes) were used as markers for lysosome and mitochondria, respectively, following the manufacturer’s instructions. FTY720 delivery and accumulation was evaluated by confocal microscopy at ×63 magnification for Lysotracker co-staining or at ×40 magnification for MitoTracker co-staining (Leica Microsystems).

Lipid quantification by mass spectroscopy

RNK-16 cells were treated with DMSO or 10 μM FTY720 for 6, 16, and 24 hours. Sphingolipids from these cells were then analyzed by electrospray ionization–tandem mass spectrometry (ESI-MS/MS) based on the method described previously.11 Briefly, 5 × 10^5 of cells were homogenized by sonication in a 10 mM Tris buffer (pH = 7.2). These samples then were subjected to lipid extraction by the use of chloroform/methanol/water as originally described by Bligh and Dyer12 after internal standards had been added (C17:sphingosine-1-phosphate, C17:sphingosine, C17:sphinganine, C17:sphinganine-1-phosphate, C17-ceramide). Sphingoid bases and 1-phosphates were separated by HPLC (Agilent 1100) with a C18 reverse phase column, and ceramide was separated on a LC-NH2-amino column before detection via multiple reaction monitoring (MRM) and quantification with an inline ABI 4000 mass spectrometer (a hybrid quadrupole-ion trap mass spectrometer; Applied Biosystems). The peak areas for the different sphingolipid subspecies were quantified according to the internal standards and normalized to cell numbers.

Animal studies

Animal experimentation was performed according to protocols approved by the Institutional Animal Care and Use Committee at the Pennsylvania State College of Medicine. Male F344 rats of approximately 6 weeks of age were obtained from Charles River Laboratories. One million RNK-16 cells, an in vivo NK-cell leukemia cell line (provided by Dr Craig Reynolds, National Cancer Institute), were IP transplanted into each of F344 rats. Five weeks after inoculation, leukemic rats were then injected intraperitoneally with 4.5 mg/kg FTY720 or PBS every day over a 4-week treatment period. Rats losing 20% body weight were most likely affected by NK-cell leukemia and were euthanized. At necropsy,
FTY720 induces apoptosis in PBMCs from one aggressive NK-cell leukemia patient and 3 chronic NK-cell leukemia patients (CD3−CD56+ cells > 80%), or pooled enriched NK cells (CD3−CD56− cells > 80%−95%) from 10 normal human donors, then resolved in the SDS-PAGE gel loading buffer in a boiling water bath for 5 minutes. Western blot analysis was performed to detect the resolution of Mcl-1. GAPDH was used as a loading control. (B) Knockdown of Mcl-1 induces apoptosis in leukemic NK cells. Human NK cells were infected with the concentrated PLKO.1 Mcl-1 shRNA or scramble shRNA lentiviral stocks for 48 hours, and then apoptosis assay was performed. *P < .05 indicates significant difference in apoptosis of Mcl-1 shRNA-infected cells compared with control shRNA-infected cells (Student t test). (Inset) Western blot analysis was performed for Mcl-1 in the control shRNA or Mcl-1 shRNA-infected NKL cells 48 hours after infection. The equal loading of protein was confirmed by probing with GAPDH Ab. (C) Dose-dependent reduced expression of Mcl-1 after FTY720 treatment. Western blot analysis was performed for Mcl-1 after 24-hour treatment of RNK-16 cells or PBMC cells from an NK-cell leukemia patient, with 2.5, 5, and 10μM FTY720. Data are representative of 3 independent experiments on RNK-16 cells or PBMCs from 3 chronic NK-cell leukemia patients. (D) Time-dependent decreased expression of Mcl-1 after FTY720 treatment. Western blot analysis was performed for Mcl-1 after treatment of RNK-16 cells with 10μM FTY720 for 6 and 24 hours, or PBMCs from an NK-cell leukemia patient with 5μM FTY720 for 2 and 6 hours. Data are representative of 3 independent experiments on RNK-16 cells or PBMCs from 3 chronic NK-cell leukemia patients.

FTY720 triggers caspase-dependent apoptotic cell death in leukemic but not normal NK cells

FTY720 exerts apoptotic effects in some human leukemic cells in vitro.6,7 Therefore, we wanted to determine whether it can induce apoptosis in leukemic NK cells. Initial experiments demonstrated that FTY720 produced dose-dependent apoptotic cell death in NKL, an aggressive human NK-cell leukemia cell line (Figure 1A) and RNK-16, an aggressive rat NK leukemia cell line (Figure 1B). We thought it important to validate the apoptotic effect of FTY720 observed in cell lines in patient samples. Indeed, we found that FTY720 induced apoptosis in PBMCs from one aggressive NK-cell leukemia patient and 3 chronic NK-cell leukemia patients (CD3−CD56+ cells > 80%, Figure 1C). Because limited material was available from patients with aggressive NK-cell leukemia, we used aggressive NK-cell leukemia cell lines throughout the remainder of the manuscript for further mechanistic studies. Such experiments showed that FTY720 resulted in time-dependent apoptosis of NKL (supplemental Figure 1A, available on the Blood Web site; see the Supplemental Materials link at the top of the online article), RNK-16 (supplemental Figure 1B), as well as PBMCs from 3 chronic NK-cell leukemia patients (CD3−CD56+ cells > 80%, supplemental Figure 1C). In contrast, treatment with 10μM FTY720 had no effect on viability of normal PBMCs (supplemental Figure 2A), and did not induce apoptosis in normal NK cells (supplemental Figure 2B). Moreover, we demonstrated that the FTY720-induced apoptosis in patients’ PBMCs occurred via cleavage of caspase 3 and PARP, the hallmarks of caspase-dependent apoptosis (supplemental Figure 3A). Furthermore, inhibition of caspase activity via z-VAD-fmk could block FTY720-induced cell death in leukemic NK cells, suggesting that the apoptosis by FTY720 was caspase-dependent (supplemental Figure 3B).

FTY720-induced apoptosis in leukemic NK cells is dependent on degradation of Mcl-1 and not activation of PP2A

To further investigate the mechanism of FTY720-induced apoptosis, we focused our attention on Mcl-1, which plays an important role in apoptosis resistance in leukemic T LGL cells.13 Leukemic
NK cells expressed high levels of Mcl-1 whereas normal NK cells did not (Figure 2A). Furthermore, efficient shRNA-mediated knockdown (80%) of Mcl-1 (Figure 2B inset) resulted in a 5.5-fold increase in apoptosis in the human NKL cell line (Figure 2B). We found that FTY720 treatment of leukemic NK cells led to significant reduction in Mcl-1 protein levels in a dose- and time-dependent fashion (Figure 2C-D). Down-regulation of Mcl-1 by FTY720 did not occur at the transcriptional level (supplemental Figure 4). Therefore, we investigated protein turnover pathways in leukemic NK cells. Notably, bafilomycin A1, a lysosomal inhibitor, but not MG132, a proteosomal inhibitor, restored Mcl-1 expression in FTY720-treated cells (Figure 3A), and rescued FTY720 induced cell death (Figure 3B). These data lend support to the hypothesis that FTY720 might down-regulate Mcl-1 via the lysosomal degradation pathway. Indeed, we demonstrated in a dose-dependent manner release of lysosomal enzyme cathepsin B, the most abundant cysteine protease in the lysosome, to cytosol in RNK-16 cells following FTY720 treatment (Figure 3C). Furthermore, colocalization of NBD-FTY720 and Lysotracker Red in RNK-16 cells confirmed that FTY720 accumulation occurs in cellular lysosomes but not in mitochondria at 2 hours after treatment, implicating FTY720 as a direct cause of lysosomal membrane permeabilization (LMP) in leukemic NK cells (Figure 3D). In addition, NAC, a reactive oxygen species (ROS) scavenger, can also restore Mcl-1 expression (supplemental Figure 5A) and rescue FTY720-induced apoptosis (supplemental Figure 5B) in RNK-16 cells, supporting the notion that FTY720 decreased expression of Mcl-1 via ROS production.

Previous studies had determined that FTY720-induced apoptosis in leukemic cells was PP2A-dependent. In contrast, pretreatment with okadaic acid, a specific PP2A inhibitor, did not result in inhibition of FTY720-induced cell death in either patient leukemic cells (supplemental Figure 6A) or rat RNK-16 cells (supplemental Figure 6B); furthermore, direct measurement of PP2A phosphatase activity showed no change in human NKL cells on FTY720 treatment (supplemental Figure 6C). These data show that FTY720 induced apoptosis in leukemic NK cells is not dependent on activation of PP2A.

Lipidomic analyses demonstrate increased levels of proapoptotic sphingosine after FTY720 treatment of leukemic NK cells

Lipidomic analyses to determine the effects of FTY720 on sphingolipid metabolites are limited to one study. That report demonstrated increased levels of proapoptotic lipid sphingosine in endothelial cells after FTY720 treatment. Therefore, to investigate an additional mechanism for FTY720-induced apoptosis in leukemic NK cells, we were interested in evaluating the sphingolipid metabolites in leukemic NK cells after FTY720 treatment. Importantly, we found that levels of the proapoptotic sphingolipid, sphingosine, but not ceramide, were increased in FTY720-treated RNK-16 cells in a time-dependent manner (Figure 4A). Prosurvival lipid sphingosine 1-phosphate (S1P) levels were not significantly altered (data not shown). Moreover, administration of sphingosine led to an increase in apoptosis in PBMCs from
CLU were assayed for apoptosis by flow cytometry. (B) PBMCs from 3 chronic NK-cell leukemia patients (CD3+CD8a+ NK cells in the blood, marrow, and spleen, thereby document complete remission (Figure 5B). Of interest, even in the 11 leukemic rats not achieving remission, FTY720 treatment resulted in a significant reduction of NK cells in these tissues, although to a lesser extent (Figure 5C). Examination of spleen sections from rats responsive to FTY720 showed normal splenic histology (supplemental Figure 7A). In contrast, leukemic rats not achieving remission showed leukemic NK-cell infiltration of the red pulp and depletion of the white pulp (supplemental Figure 7A). Moreover, we found that Mcl-1 was significantly averted in the spleens of responsive rats, indicating that it may be a unique target of FTY720 in NK-cell leukemia (supplemental Figure 7B). These data suggest that in vivo therapeutic efficacy of FTY720 may be a consequence of modulation of Mcl-1 signaling which led to resolution of leukemic cell infiltration. Previously, we demonstrated that nonapoptotic ceramide induced complete remission in this rat model by targeting survivin.13 FTY720 treatment of NKL or RNK-16 cells in vitro had no effect on level of survivin protein (data not shown). Given that FTY720 and C8-ceramide have distinct cellular targets in leukemic NK cells, we were interested in examining whether combining these 2 drugs would enhance therapeutic efficacy in leukemic NK cells in vivo. Indeed, we found that treatment with the combination of FTY720 and nonapoptomosomal C8-ceramide induced apoptosis with a synergistic effect in NKL cell line and with an additive effect in RNK-16 cells (supplemental Figure 8). These data provide a rationale for further investigating such combined treatment in vivo, using the preclinical Fischer rat model of NK-cell leukemia.

**Discussion**

Our studies show that FTY720 led to apoptosis in leukemic NK cells from patients with chronic NK-cell leukemia and from NK-cell leukemia cell lines in vitro as well as complete remission in a rat model of aggressive NK-cell leukemia. There is an urgent unmet need for development of new therapeutics for both NK-cell leukemia. This is particularly important for aggressive disease. Combination chemotherapy is usually not successful in achieving remission and median survival is only a few months for this fatal illness. We found that FTY720 induced apoptosis in NK-cell leukemia by 2 mechanisms: degradation of prosurvival protein Mcl-1 and altered sphingolipid metabolism resulting in accumulation of proapoptotic sphingosine. We focused first on the effect of FTY720 on expression of Mcl-1, which has been reported to play...
an essential survival role in T-LGL leukemia. Interestingly, we found that Mcl-1 was highly expressed in human leukemic NK cells while it is undetectable in normal NK cells (Figure 2A). Moreover, we also showed that efficient knockdown of Mcl-1 led to 5.5-fold increase of apoptosis in leukemic NK cells, demonstrating the important survival role of Mcl-1 in leukemic NK cells.

Because FTY720 did not affect transcription of Mcl-1, we examined whether Mcl-1 was degraded by FTY720 in leukemic NK cells. Having demonstrated this to be the case, we next examined mechanisms of degradation. A widely accepted mechanism for regulation of Mcl-1 expression after death stimulus activation involves proteosomal degradation. However, a proteosomal inhibitor, MG132, had no effect on the reduced levels of expression of Mcl-1 protein and apoptotic cell death produced by FTY720 treatment, suggesting that degradation of Mcl-1 by FTY720 was not through proteosomal pathway. Interestingly, we found that FTY720 was delivered to lysosome of leukemic NK cells. Further investigation how FTY720 triggers lysosomal degradation pathway, we examined the influence of FTY720 on oxygen species (ROS) because of the fact that lysosomes are particularly sensitive toward oxidative stress. Production of ROS after FTY720 treatment had been shown previously in hepatocellular carcinoma. Indeed, we showed that a free radical scavenger NAC restored Mcl-1 expression and rescued FTY720-induced apoptosis in leukemic NK cells. These data suggest that FTY720 regulation of Mcl-1 expression occurs through a novel mechanism involving ROS production.

We were also interested in examining sphingolipid metabolism after FTY720 treatment of leukemic NK cells. Sphingolipids are key components of the lipid bilayer of membranes and also are vital second messengers involved in cell survival, proliferation and apoptosis within a cell. The balance between sphingolipid metabolites S1P and ceramide/sphingosine (CER/SPH), the upstream precursors of S1P, is believed to provide a rheostat mechanism that determines whether a cell proliferates or undergoes apoptosis. In contrast to the growth-inhibitory and proapoptotic effects of ceramide and sphingosine, S1P, which is produced by phosphorylation of sphingosine in a reaction catalyzed by sphingosine kinase, promotes cell growth and survival. Previously, it had been shown that high micromolar doses of FTY720 can inhibit
sphingosine kinase 1 activity, leading to accumulation of sphingosine.14,32 Depending on the cell lines and experimental procedures used, sphingosine has been shown to mediate apoptosis as a putative second messenger via activation of JNK and p38 and inhibition of ERK/MAPK, PKC, and Akt.33,37 Importantly, we found increased levels of sphingosine but not ceramide, in leukemic NK cells treated with FTY720. Sphingosine led to increase in apoptosis in leukemic NK cells but to a much lesser extent than treatment with the same dose of FTY720 (Figure 4B-C). These data suggest that efficacy of FTY720 in NK-cell leukemia might also be attributed in part to altered sphingolipid metabolism.

We have previously shown that targeting survivin by nanoliposomal ceramide induced complete remission in F344 rat NK-cell leukemia model.17 Mitochondrial survivin was a critical ceramide target responsible for the efficacy of liposomal ceramide therapeutics.17 Interestingly, FTY720 targeted Mcl-1 but not survivin expression, indicating a unique mechanism causing apoptosis of leukemic NK cells. Furthermore, sphingolipidomics profiling (Figure 4A) showed that ceramide levels were not altered by FTY720 treatment, suggesting FTY720 therapeutics in NK-cell leukemia is independent of ceramide/survivin signaling. Because these therapeutics target different components of survival signaling and because we found that treatment with both FTY720 and Ceramide nanoliposome had additive/synergistic effects on leukemic NK cells, it will be interesting to investigate such combined therapies in this animal model of NK-cell leukemia.
