Studies on the Inhibition of Ellagic Acid-Activated Hageman Factor (Factor XII) and Hageman Factor Fragments

By Oscar D. Ratnoff

Hageman factor (HF, factor XII) that has been exposed to Sephadex-ellagic acid gels is a single-chain species (HF\(_{sa}\)) with amidolytic properties for the synthetic substrate H-D-phenylalanyl-l-pipecolyl-l-arginine \(p\)-nitroanilide. Earlier we reported that amidolysis was suppressed by incubation of HF\(_{sa}\) with specific antiserum. The present study provides additional evidence that the amidolytic properties of preparations of HF\(_{sa}\) are ascribable to this substance through an examination of a number of protease inhibitors. HF\(_{sa}\)'s amidolytic properties were inhibited by \(\alpha_2\)-plasmin inhibitor, antithrombin III in the presence of heparin, and Cl esterase inhibitor (CI-INH). Additionally, it was inhibited by popcorn inhibitor, leupeptin, hexadimethrine bromide, prothrombinase, dansyl-arginine N-(3-ethyl-1,5-pentene-diyi) amide (DAPA), diisopropylphosphofluoridate (DFP), aprotinin, and at excessively high concentrations, soybean and lima bean trypsin inhibitors. The spectrum of action of agents that did or did not inhibit HF\(_{sa}\) supports the view that amidolysis by preparations of HF\(_{sa}\) is attributable to this enzyme. In general, the enzymatically active carboxy-terminal fragment of HF (HF\(_{s}\)) was inhibited by the same agents that inhibited HF\(_{sa}\), but aprotinin, prothrombinase and hexadimethrine bromide were more effective against HF\(_{s}\), than HF\(_{sa}\), while the reverse was true of lima bean trypsin inhibitor.

Preparations of purified Hageman factor (HF, factor XII) that have been exposed to Sephadex-ellagic acid gels have amidolytic properties and, in the presence of high molecular weight (HMW) kininogen, enhance formation of thrombin via the intrinsic pathway by activated plasma thromboplastin antecedent (PTA, factor XI). The possibility exists that amidolysis by such preparations of ellagic acid-treated HF (HF\(_{sa}\)) is due to trace contamination with other amidolytic enzymes. Experiments reported here of the inhibitory properties of various agents appear to fortify the view that amidolysis is a property of HF\(_{sa}\). Inhibition of enzymatically active fragments of HF (HF\(_{s}\)) by the agents tested paralleled inhibition of HF\(_{sa}\).

Materials and Methods

Purified HF, prepared as previously described, was a single-chain species, as assessed by sodium dodecylsulfate polyacrylamide gel electrophoresis (SDS-PAGE) after reduction; approximately 3-5 \(\mu\)g protein was tested in this assay. It was depleted of other known factors of the contact-activated clotting system, including prekallikrein, HMW kininogen, PTA, and plasminogen. Two preparations of HF were used, with specific activities of 46 and 113 U/mg protein, as measured in clotting assays; one unit of HF is that amount found in 1 ml of a pool of 24 plasmas derived from normal male subjects.

HF\(_{sa}\) was prepared as described by mixing HF in the presence of bovine albumin with Sephadex-ellagic acid gels. The HF\(_{sa}\), in barbital-saline buffer containing 0.05% bovine albumin, was separated by centrifugation. It possessed, on the average, 0.13 ± S.D. 0.04 U/ml (4.6 \(\mu\)g/ml) of total HF, and 0.03 ± 0.01 U/ml (1.1 \(\mu\)g/ml) of coagulant HF, as tested respectively by a modified partial thromboplastin time technique in the presence of kaolin or in the absence of a clot-promoting surface; on the average, HF\(_{sa}\) hydrolyzed 2.1 nmoles S2238/\(\mu\)g HF\(_{sa}\)/ml/min (see below).

HF\(_{s}\) was prepared by tryptic digestion of purified HF, as reported earlier. The preparations used possessed a single species with a MW of about 30,000, as estimated by SDS-PAGE, and contained 17 to 47 \(\mu\)g of protein per ml of barbital-saline buffer. Before use, HF\(_{s}\) was further diluted in the same buffer to 2.7 (SD ± 1.3) \(\mu\)g/ml.

On the average, the diluted HF\(_{s}\) hydrolyzed 1.14 nmoles S2238/\(\mu\)g HF\(_{s}\)/ml/min. S-D-phenylalanyl-l-pipecolyl-l-arginine \(p\)-nitroanilide (S2238, Kabi Diagnostica, Stockholm), was dissolved in water at a concentration of 1 mM and mixed before use with an equal volume of Tris-imidazole-saline buffer.

The inhibitors tested included soybean trypsin inhibitor (SBTI), lima bean trypsin inhibitor (LBTI), and ovomucoid (all from Worthington Biochemical Corp., Freehold, N.J.), diisopropylphosphofluoridate (DFP, 0.12 \(M\) in absolute ethanol) and \(\alpha_2\)-antitrypsin (salt-free, 8 mg/ml) (both from Sigma Chemical Co., St. Louis), hexadimethrine bromide (Aldrich Chemical Co., Milwaukee, Wisc.), hirudin (2500 ATU/mg protein, Medimpex, Budapest), aprotinin (Trasylool, 10,000 U/ml, the gift of Farbenfabriken/Bayer AG Leverkusen, West Germany), heparin (USP, beef lung, 1000 U/ml of 0.9% sodium chloride solution with 0.9% benzyl alcohol, Upjohn Co., Kalamazoo, Mich.), and prothrombin sulfate (10 mg/ml, Eli Lilly and Co., Indianapolis, Ind.). Antithrombin III (25 U/ml, Kabi Diagnostica) was said to be 5 U/mg, but studies of its ability to neutralize thrombin activity, as measured by amidolysis of S2238, suggested that its activity was closer to 1 U/mg. CI esterase inhibitor (CI-INH), 54.6 U/mg protein, was the gift of Dr. J. Pasky, Cleveland; \(\alpha_2\)-plasmin inhibitor, 1.32 mg/ml of 0.15 \(M\) sodium chloride in 7% albumin, 0.01 U/ml (1.1 \(\mu\)g/ml) of coagulant HF, as tested respectively by a modified partial thromboplastin time technique in the presence of kaolin or in the absence of a clot-promoting surface; on the average, HF\(_{sa}\) hydrolyzed 2.1 nmoles S2238/\(\mu\)g HF\(_{sa}\)/ml/min (see below).

Hageman factor (HF, factor XII) that has been exposed to Sephadex-ellagic acid gels is a single-chain species (HF\(_{sa}\)) with amidolytic properties for the synthetic substrate H-D-phenylalanyl-l-pipecolyl-l-arginine \(p\)-nitroanilide. Earlier we reported that amidolysis was suppressed by incubation of HF\(_{sa}\) with specific antiserum. The present study provides additional evidence that the amidolytic properties of preparations of HF\(_{sa}\) are ascribable to this substance through an examination of a number of protease inhibitors. HF\(_{sa}\)'s amidolytic properties were inhibited by \(\alpha_2\)-plasmin inhibitor, antithrombin III in the presence of heparin, and CI esterase inhibitor (CI-INH). Additionally, it was inhibited by popcorn inhibitor, leupeptin, hexadimethrine bromide, prothrombinase, dansyl-arginine N-(3-ethyl-1,5-pentene-diyi) amide (DAPA), diisopropylphosphofluoridate (DFP), aprotinin, and at excessively high concentrations, soybean and lima bean trypsin inhibitors. The spectrum of action of agents that did or did not inhibit HF\(_{sa}\) supports the view that amidolysis by preparations of HF\(_{sa}\) is attributable to this enzyme. In general, the enzymatically active carboxy-terminal fragment of HF (HF\(_{s}\)) was inhibited by the same agents that inhibited HF\(_{sa}\), but aprotinin, prothrombinase and hexadimethrine bromide were more effective against HF\(_{s}\), than HF\(_{sa}\), while the reverse was true of lima bean trypsin inhibitor.
the gift of Dr. T. Takaya, the Protein Research Foundation, Osaka, Japan; and dansylarginine N-(3-ethyl-1,5-pentanediyl) amide (DAPA), was the gift of M. Nesheim, Mayo Clinic, Rochester, Minn. Except for DFP, all inhibitors were dissolved in or diluted as indicated in barbital-saline buffer.

Barbital-saline buffer (pH 7.5) was 0.025 M barbital in 0.125 M sodium chloride. Tris-imidazole-saline buffer (pH 8.2) was 0.025 M tris (hydroxymethyl)aminomethane (Sigma), 0.025 M imidazole (Matheson, Coleman and Bell, Norwood, Ohio) and sufficient sodium chloride to provide an ionic strength of 0.15.

Inhibition of amidolysis by plasma inhibitors of proteolysis was tested by incubating 0.15 ml of HF or HF, for 30 min at 37°C with 0.1 ml of serial dilutions of the reagents to be tested in barbital-saline buffer, or buffer alone. Thereafter, 1.0 ml of 0.5 mM S2238 in Tris-imidazole-saline buffer, prewarmed to 37°C, was added and incubation was continued for 60 min. The reaction was then stopped by addition of 0.3 ml glacial acetic acid. The amount of p-nitroaniline (p-NA) released was read at 405 nm in 10 mm cuvettes in comparison to a blank in which acetic acid was added before addition of substrate. The optical density was compared to that of a standard solution of p-NA.

The effect of other inhibitors (except DFP) was tested in the same manner except that the preliminary incubation period was 10 min. DFP, 0.12 M in absolute ethanol, 2.55 µl, was added to 0.15 ml HF or HF, to bring the DFP concentrate to 2 × 10^{-3} M, and the mixture was incubated for 10 min. Thereafter 97.45 µl of barbital-saline buffer was added. Only this concentration of DFP was tested. The concentrations of HF and HF, used were selected to release approximately 15 to 18 nmole of p-NA per ml of enzyme-substrate mixture in 60 min.

RESULTS

The amidolytic activity of HF, was readily inhibited by a2-plasmin inhibitor, CI-1NH and a mixture of antithrombin III and heparin (Table 1). Approximately the same concentrations inhibited HF,. In contrast, neither antithrombin III in the absence of heparin, a2-macroglobulin nor a1-antitrypsin inhibited HF or HF, at the concentrations tested (Table 3).

Amidolysis by both HF and HF1 was inhibited by 2 × 10^{-3} M DFP; lesser concentrations were not tested (Table 2). Both enzymes were comparably inhibited by popcorn inhibitor, leupeptin, and DAPA. In contrast, relatively more hexadimethrine bromide, protamine sulfate, and aprotinin were needed to induce inhibition of HF than HF, SBTI and LBTI were inhibitory only at very high concentrations.

Several other protease inhibitors did not block amidolysis by HF, or HF, under the conditions examined (Table 3). In an earlier study,3 we noted that amidolysis by HF and HF, was enhanced by addition of high molecular weight kininogen, albumin, cytochrome C, and, to a much lesser extent, IgG. The degree of enhancement was much greater for HF1 than for HF, presumably because the latter preparation already contained 0.5 mg albumin/ml (see Materials and Methods). In the present study, a1-antitrypsin, a2-macroglobulin, ovomucoid and SBTI enhanced amidolysis by HF, and HF,

DISCUSSION

Hageman factor (HF, factor XII) that has been exposed to Sephadex-ellagic acid gels (HF,) hydrolyzes the synthetic amide H-D-phenylalanyl-L-pipercolyl-L-arginine p-nitroanilide (S2238).5 Revak et al.5 provided evidence that, in plasma, activation of HF depends upon its scission, first internally within a disulfide loop and then into two portions, an amino-terminal fragment (HF,) of MW 28,000; the latter bears the enzymatically active group.

†Enhancement of amidolysis.
‡Higher concentrations enhanced amidolysis.
HF\textsubscript{ca}, in contrast, is a single-chain species with a MW of about 80,000.\textsuperscript{1} The possibility exists that its amidolytic properties reflect the unsuspected presence of other plasma proteases that are either themselves amidolytic or might be responsible for scission of HF\textsubscript{ca} subsequent to its incubation with its substrates. Earlier we reported that amidolysis was suppressed by incubation of HF\textsubscript{ca} with specific antiserum, supporting the specificity of the observed enzymatic activity.\textsuperscript{1} The present study provides additional evidence that the amidolytic properties of preparations of HF\textsubscript{ca} are ascribable to this substance through an examination of the inhibitory properties of a number of agents chosen for their possibly differentiating properties.

The clearest separation of HF\textsubscript{ca} from plasma proteases other than HF\textsubscript{f} was seen in its inhibition by popcorn inhibitor. Hojima and his associates\textsuperscript{8,9} recently reported that one or more proteins derived from sweet corn or popcorn inhibited amidolysis by HF\textsubscript{f}. These agents were without effect upon \(\alpha\)-thrombin, activated Stuart factor (factor Xa), or plasma kallikrein. Additionally, popcorn inhibitor does not block the actions of activated PTA (factor XIa), activated Christmas factor (factor IXa) or factor VII, as tested in clotting assays, nor of the activated form of the first component of complement (C\(\text{I}\)), as determined by esterolysis of N-acetyl-L-tyrosine ethylester.\textsuperscript{8}

Although these studies tell us that preparations of HF\textsubscript{ca} possessed unique amidolytic properties, they do not rule out the presence of contaminating enzymes. Studies of other inhibitors, however, demonstrated that the amidolytic properties of HF\textsubscript{ca} were not blocked by a variety of substances that inhibit other known plasma proteases. Thus plasminostreptin, an inhibitor of plasmin found in cultures of \textit{Streptomyces antifibrinolyticus},\textsuperscript{9} and hirudin, which specifically blocks the action of thrombin\textsuperscript{10} and probably activated Christmas factor,\textsuperscript{11} were without effect upon amidolysis by HF\textsubscript{ca}. Similarly, \(\alpha\)-antitrypsin, which inhibits activated PTA,\textsuperscript{12} \(\alpha\)-macroglobulin, which inhibits plasma kallikrein\textsuperscript{13} and plasmin,\textsuperscript{14} and tranexamic acid, which inhibits plasmin\textsuperscript{15} were without effect upon HF\textsubscript{ca}. Soybean trypsin inhibitor (SBTI), which in small concentrations blocks the actions of plasmin,\textsuperscript{16} plasma kallikrein\textsuperscript{17} and activated Stuart factor\textsuperscript{18} had only minimal activity against HF\textsubscript{ca} at excessively high concentrations.

These studies do not rule out contamination of HF\textsubscript{ca} with C\(\text{I}\), but preparations of HF\textsubscript{ca} do not hydrolyze N-acetyl-L-tyrosine ethyl ester, a specific substrate of C\(\text{I}\) (unpublished observations). Nor do they rule out contamination with factor VII, whose amidolytic properties were not tested.

A number of other agents that inhibited the action of HF\textsubscript{ca} also inhibit other proteases, and thus were not helpful in the present context. For example, although hexadimethrine bromide and protamine sulfate inhibited HF\textsubscript{ca}, these agents also block the clot-promoting properties of activated Stuart factor.\textsuperscript{19} Similarly, leupeptin inhibits plasmin, C\(\text{I}\), C\(\text{I}\)\(\text{a}\), plasma kallikrein, thrombin,\textsuperscript{20} activated Stuart factor, and activated PTA (unpublished observations).

In general, HF\textsubscript{f} was inhibited only by those agents that inhibited HF\textsubscript{ca}. Notably, however, aprotinin, protamine sulfate and hexadimethrine bromide were more effective against HF\textsubscript{f} than HF\textsubscript{ca}, while the reverse was true for LBTI.

In sum, the inhibitory spectrum of HF\textsubscript{ca} appeared to differentiate this enzyme from other plasma proteases, in agreement with the view that the amidolytic properties of this preparation are attributable to a single-chain, activated species of Hageman factor.

ACKNOWLEDGMENT

This study was made possible by the expert technical assistance of Barbara Everson and Marilyn Vavrek. Dr. Kenneth E. Neet aided in interpretation of data.
