Abstract

We recently demonstrated that IgE, in the absence of crosslinking agents, activates signaling pathways in normal murine bone marrow derived mast cells (BMMCs) and that this activation enhances BMMC survival, at least in part, via secretion of autocrine-acting cytokines. We report herein that IgE alone also triggers the adhesion of both BMMCs and connective tissue mast cells (CTMCs) to the connective tissue component, fibronectin (FN). This adhesion occurs to the same extent as that triggered by optimal levels of Steel Factor (SF) or IgE + antigen (IgE+Ag) and is mediated by an increased avidity of the integrin VLA-5. Moreover, this IgE-induced adhesion, which is prolonged compared to that elicited by SF or IgE+Ag, requires phosphatidylinositol 3-kinase (PI3K), phospholipase Cγ (PLCγ) and extracellular calcium but not Erk or p38. Interestingly, we found, using the calcium channel blocker, 2-APB and Lyn-/- BMMCs that both IgE- and IgE+Ag-induced adhesion to FN require extracellular calcium entry whereas SF does not. Furthermore, our data suggest that FN acts synergistically with IgE to prolong intracellular phosphorylation events and enhance IgE-induced inflammatory cytokine production and BMMC survival.

Introduction

Mature mast cells are located at the portals between self and non-self, and serve as front line defenders against invading bacteria and helminthic parasites. They do this by initiating an acute inflammatory response, which typically consists of a rapid degranulation that releases preformed inflammatory molecules (such as histamine, serotonin and proteases), and a subsequent secretion of de novo synthesised arachidonic acid metabolites and inflammatory cytokines.

Unfortunately, this inflammatory response can also be detrimental and lead to immediate-type allergic reactions and other inflammatory disorders like asthma, arthritis and multiple sclerosis.

Mature mast cells originate from hemopoietic stem cell derived progenitors in the bone marrow that are recruited out of the circulation and into connective tissues. This recruitment, via adhesion of integrins on the surface of mast cell progenitors to components of connective tissue, like fibronectin (FN), is thought to play a critical role in mast cell retention and subsequent proliferation, differentiation, survival, priming and activation. Various stimuli have been shown to induce the adhesion of bone marrow derived mast cells (BMMCs) to FN, via the integrins \( \alpha_4 \beta_1 \) and \( \alpha_5 \beta_1 \) (very late antigens (VLA)-4 and -5, respectively). These include physiologically relevant stimuli, such as Steel Factor (SF) and antigen-crosslinking (IgE+Ag) of the high affinity IgE receptor, Fc\( \varepsilon \)RI. While the cell surface level of VLA-4 decreases with BMMC differentiation, that of VLA-5 remains high and appears to be the predominant integrin involved in mature mast cell adhesion to FN.
We recently demonstrated that IgE, in the absence of crosslinking agents, stimulates multiple signalling pathways in normal BMMCs grown in suspension cultures and that this leads to an increased survival of these cells in the absence of exogenous cytokines \(^\text{16}\). We went on to show that this enhanced survival is due, at least in part, to IgE maintaining Bcl-X\(_L\) levels and up-regulating the production of autocrine-acting cytokines \(^\text{16}\). In the work reported herein we have explored the possibility that IgE alone might also affect biological responses other than survival. Specifically, we asked if IgE alone could enhance the adhesion of mast cells to FN.
Materials and Methods

Generation of Mast Cells

BMMCs were derived from 4- to 8-week-old SHIP+/+ and -/- C57B6 or Lyn+/+ and -/- C57B6 mice as described previously. By 8 weeks in culture, greater than 98% of the cells were c-kit and FcεRI positive, as assessed by fluorescein isothiocyanate (FITC)-labeled anti-c-kit antibodies (BD PharMingen, Mississauga, Canada) and FITC-labeled IgE (anti-erythropoietin 26), respectively. Connective tissue mast cells (CTMCs) were derived from SHIP+/+ C57B6 BMMCs by co-culturing with Swiss 3T3 fibroblasts as described. After 2 weeks of co-culture more than 90% of the adherent mast cells were safranin positive.

IgEs

Unless indicated, mouse monoclonal SPE-7 anti-DNP IgE (Sigma, St. Louis, MO) or monomeric SPE-7, prepared as described previously, was used throughout. Where indicated, TNP-lysine affinity purified, mouse monoclonal Liu anti-DNP (H1 26.82) or anti-kappa chain affinity purified, mouse monoclonal anti-Epo26 (StemCell Technologies Inc., Vancouver, BC) was used. All IgEs were titred using an IgE ELISA (BD PharMingen, San Diego, CA).

Adhesion Assay

96-well Nunc Maxisorp plates (NUNC, Naperville, IL) were coated with 50 µg/ml human FN (Sigma) in PBS for 2 h at 37°C or 16 h at 4°C, washed 3 times with PBS, blocked with 3% BSA (Sigma) in HBSS (Hank's Balanced Salt Solution-Modified; StemCell Technologies Inc.), for 1 h at 37°C, then washed 3 times with HBSS + 0.03% BSA (assay medium). For stimulation with IgE or SF, BMMCs or CTMCs were washed with RPMI (without phenol red) + 0.1% BSA,
resuspended at 1×10^6 cells/ml and labelled with 3 μg/ml Calcein-AM (Molecular Probes, Eugene, OR) for 20 min at 37°C. For stimulation with IgE+Ag, BMMCs or CTMCs were preloaded with 1 μg/ml IgE overnight at 37°C in the absence of FN, washed twice to remove unbound IgE, then resuspended and labelled as above. After labelling, cells were washed and resuspended at 1×10^6 cells/ml in assay medium. 50 μl of assay medium ± IgE, SF or DNP-HSA (Sigma) was added to each FN-coated well followed by 50 μl of the cell mixture and incubated at 37°C for the indicated times. The degree of adhesion was quantitated using a Cytofluor 2300 Microplate Reader (Millipore, Bedford, MA) and is expressed as the percentage fluorescence remaining in the wells after washing away unbound cells. Treatment of cells with inhibitors or antibodies was carried out by incubating Calcein-AM labelled cells ± DMSO, LY294002, Compound 3 (bisindolylmaleimide I, HCl), PD98059, U0126, apigenin, U73122, SB203580, Gö6976 (all from Calbiochem, La Jolla, CA), 2-aminoethoxydiphenyl borate (2-APB; Sigma), or anti-CD49e (BD PharMingen) for 30 min at 37°C (inhibitors) or 23°C (antibodies) prior to the addition of the cells and inhibitors (or antibodies) to the assay plate. The peptides GRGDSP and GRGESP were from Invitrogen Life Technologies (Carlsbad, CA). For experiments without calcium, Calcein AM loaded cells were washed 3 times with Dulbecco's PBS and the assays carried out in this medium. A 2-tailed paired Student's t test was used to determine statistical significance between adhesion values.

**BMMC Stimulation and Western Blotting**

To compare IgE- versus IgE+FN-induced signalling events, BMMCs were starved overnight in IMDM + 10% FCS, resuspended at 1x10^6 cells/ml in IMDM + 0.1% BSA, aliquoted (2 ml/well) into either 6-well tissue culture plates (Falcon) or BIOCOAT® human FN-coated 6-well tissue
culture plates (Falcon) and stimulated with 5 μg/ml IgE for the indicated times. The plates were then placed on ice, 4°C HBSS added and, in the case of the standard tissue culture plates the cells (which were in suspension) pelleted and lysed in PSB containing 0.5 % NP40. For the FN-coated plates, the non-adherent cells were washed away and the adherent cells lysed in PSB containing 0.5% NP40. 50 μg of protein was loaded/lane (based on BCA assays; Pierce, Rockford, IL) and separated by SDS-PAGE.

To test the specificities and potencies of the inhibitors used in the adhesion assays, BMMCs were starved for 4 h, resuspended at 1x10^6 cells/100 μl IMDM + 0.1% BSA and incubated for 15 min at 37°C with the inhibitors at various concentrations before adding 5 μg/ml IgE or 100 ng/ml SF for 5 min. Cells were solubilized by boiling for 1 min with SDS-sample buffer (using 1x10^6 BMMCs/sample for total cell lysates). The phospho-PKB (Ser^473), phospho-Erk1/2 and phospho-p38 antibodies were from Cell Signalling Technologies (Beverly, MA). The Erk1 and 4G10 antibodies were generous gifts from Drs. Steven Pelech and Brian Druker, respectively.
**ELISAs**

BMMCs were starved for 4 h in IMDM + 10% FCS, resuspended at 1x10^6 cells/ml in IMDM + 0.1% BSA and added to FN- or BSA-coated polystyrene beads (bead:cell ratio 1:1) ± IgE and incubated at 37°C for the indicated times. To coat the beads, Polybead® Polystyrene Microsphere 15 µ beads (Polysciences, Warrington, PA) were incubated for 1 h at 23°C with 1 mg/ml human FN, then blocked with 3% BSA in HBSS for 30 min at 23°C or incubated with 3% BSA in HBSS for 1.5 h at 23°C as described. IL-6 and TNFα (BD PharMingen) ELISAs were performed with bead supernatants according to the manufacturer’s instructions.

**FACS Analysis**

BMMCs were washed and resuspended at 5x10^5 cells/ml in IMDM + 0.1% BSA ± 5 µg/ml IgE and incubated in 6-well tissue culture plates or BIOCOAT® human FN-coated 6-well plates (1ml/well) at 37°C for 1 or 4 h. Cells were then harvested, washed once with HBSS + 2% FCS + 0.05% NaN₃ (HFN) and resuspended in 50 µl HFN + 1 µg anti-CD49e or an isotype control and incubated for 30 min at 4°C. After washing, the cells were incubated with PE-conjugated anti-rat IgG (Jackson Labs, West Grove, PA) for 30 min at 4°C, washed twice, resuspended in HFN and analysed using the FACSCalibur (Becton Dickinson).

**Calcium measurements**

Calcium fluxes were measured as described previously. For stimulation with IgE or SF, BMMCs were incubated with 2 µM fura-2/AM (Molecular Probes) in Tyrode’s buffer at 23°C for 45 min, washed twice, resuspended in Tyrode’s buffer at 5x10^5 cells/ml in a stirring cuvette and stimulated with the indicated concentrations of IgE or SF. For stimulation with IgE+Ag, 5
μg/ml IgE was added during the fura-2 loading step, followed by stimulation with 20 ng/ml DNP-HSA. For the 2-APB studies, cells were labelled with fura-2 at 37°C in the presence of 50 μM 2-APB, then stimulated as above. For the EGTA studies, 5 mM EGTA was added immediately prior to the addition of the stimulus.

Survival Assay

Survival assays were carried out as described previously except that Falcon 1172 96-well flat bottom plates were first treated for 1 h at 37°C ± 50 μg/ml FN and then all the plates treated for 1 h at 37°C with 3% BSA. The wells were then washed with IMDM + 0.1% BSA and the BMMCs, after washing with IMDM, were added at 5x10^5 cells/ml in IMDM + 0.1% BSA ± IgE. Viability was assessed by trypan blue exclusion.
Results

IgE alone stimulates the adhesion of both BMMCs and CTMCs to FN

We recently demonstrated that monomeric IgE, in the absence of crosslinking agents or exogenous growth factors, was capable of enhancing the survival of BMMCs and did so, at least in part, by maintaining BclX\textsubscript{L} levels and by producing autocrine-acting cytokines\textsuperscript{16}. To determine if IgE alone had any other biological effects on BMMCs we tested its ability to stimulate the adhesion of these cells to the connective tissue component, FN. As can be seen in Fig 1A (top left panel), IgE (SPE-7) alone stimulated the adhesion of Calcein-AM loaded normal C57B6 mouse derived BMMCs to FN in a dose dependent fashion. Utilizing a 60 min adhesion assay, adhesion typically plateaued between 50-60% of input cells. The IgE concentration yielding half-maximal adhesion was found to be between 100-500 ng/ml IgE. When wells were coated with BSA instead of FN, no adhesion was observed in response to IgE (Fig 1A, top left panel). Similar results were obtained with monomeric IgE, derived by HPLC fractionation of SPE-7 IgE\textsuperscript{16}, indicating that this was not due to low levels of IgE aggregates in the IgE preparation (data not shown). As well, similar results were obtained using the Liu anti-DNP IgE\textsuperscript{19} and an anti-erythropoietin IgE (anti-Epo 26)\textsuperscript{17}, demonstrating that these results were not restricted to the SPE-7 anti-DNP IgE (Fig 1A; top right panel).

For comparison, we carried out dose response studies with SF (Fig 1A, bottom left panel) and a similar plateau was observed with optimal levels of SF, shown in previous studies to be highly effective at inducing adhesion of BMMCs to FN\textsuperscript{12}. We also found that IgE+Ag was capable of inducing BMMC adhesion to FN (Fig 1A, bottom right panel), in keeping with previous reports\textsuperscript{13,22}. For this study, BMMCs were presensitized overnight with 1 \mu g/ml IgE in the absence of FN.
and then, after washing away unbound IgE, DNP-HSA was added at the indicated concentrations. Adhesion reached a plateau similar to that obtained with IgE alone or with SF. As reported previously, the concentrations of SF and antigen that gave half maximal adhesion (ie, approximately 0.5 ng/ml and 1.5 ng/ml, respectively) were far less (10-100 fold) than that required for half maximal stimulation of proliferation \(^{11}\) or degranulation \(^{23,24}\), respectively. It is worthy of note that the background adhesion of BMMCs to FN varied from one experiment to another (from 4-18%). This variation primarily reflects differences in the basal level of adhesion between different batches of BMMCs.

It is now well documented that SF and other agents that enhance adhesion of mast cells to FN do so in a transient way \(^{11,23}\). We therefore carried out time course studies with IgE alone to determine if the kinetics of adhesion and/or release were similar to that obtained with SF or IgE+Ag. As can be seen in Fig 1B, IgE-induced adhesion of BMMCs to FN was slower (ie, undetectable at 5 min) but remained at plateau levels significantly longer than with SF or IgE+Ag. This may be due in part to the slow on rate of IgE \(^{25}\) and the slow internalization rate of uncrosslinked IgE/FceRI \(^{26}\), respectively.

We then asked if IgE alone could also stimulate the adhesion of CTMCs to FN. As shown in Fig 1C, even though background adhesion was higher with these cells, IgE, as well as SF and IgE+Ag, triggered CTMC adhesion, and the concentration of IgE that gave half maximal adhesion was approximately 500 ng/ml. Thus IgE-induced adhesion was not restricted to BMMCs.
IgE alone stimulates the adhesion of BMMCs to FN via an increase in the avidity of VLA-5

To gain some insight into the nature of the receptors on BMMCs that bind to FN in response to IgE alone, we carried out adhesion assays in the presence and absence of the peptide GRGDSP (which contains the RGD consensus sequence within FN that binds to a sub-set of integrins \(^{15}\)) or a control peptide, GRGESP. As expected from previous reports \(^{12}\), the RGD-containing peptide completely inhibited SF-induced adhesion while the control RGE-containing peptide did not, and the same results were obtained with IgE (Fig 2A). To hone in on which integrin was involved in IgE-induced adhesion to FN, we next examined the effect of blocking VLA-5 with the anti-\(\alpha_5\) integrin antibody MFR-5 (anti-CD49e) since it had been shown previously that this integrin was involved in SF- and IgE+Ag-induced adhesion of BMMCs to FN \(^{11,22}\). As can be seen in Fig 2B, this antibody also inhibited IgE-induced adhesion to FN. However, this antibody did not completely block adhesion, thus it is possible that another RGD binding receptor also contributes to IgE- and SF-induced adhesion.

To determine if IgE, in the absence of Ag, was enhancing BMMC adhesion to FN by upregulating the cell surface level of VLA-5 we carried out flow cytometry using anti-CD49e. As can be seen in Fig 2C, there was no increase in the cell surface level of \(\alpha_5\) integrin following a 1h treatment with IgE (when binding to FN is maximal (Fig 1B)). Thus IgE alone, similar to what has been reported previously with SF and IgE+Ag \(^{22}\), appeared to enhance adhesion not by upregulating integrin receptors but by increasing the avidity of VLA-5 via "inside-out"signalling. Also, there was no change in the cell surface level of \(\alpha_5\) integrin following a 4 h treatment with IgE in the presence of either BSA (Fig 2D, top panel) or FN (Fig 2D, bottom panel). This
demonstrates that the detachment of IgE-stimulated BMMCs from FN at this time was not due simply to a reduction in the level of cell surface VLA-5.
**IgE-induced adhesion of BMMCs to FN requires PI3K but not Erk or p38**

To gain some insight into the intracellular pathways through which IgE alone triggered adhesion to FN we first explored the role of the PI3K pathway since it had been shown previously to be involved in SF- and IgE+Ag-induced BMMC adhesion to FN\(^{22,27,28}\). To do this, we tested the PI3K inhibitor, LY294002, and found that it inhibited both SF- and IgE-induced adhesion of BMMCs to FN (Fig 3A). Similar results were obtained with wortmannin (data not shown). We carried out these and subsequent inhibitor studies at times and concentrations of IgE and SF that were suboptimal for adhesion to FN in order to maximize the sensitivity of the assay to potential inhibitors and minimize exposure of the cells to inhibitors. As well, we titrated the various inhibitors used via Western analyses of BMMCs stimulated for 5 min with 5 \(\mu\)g/ml IgE or 10 ng/ml SF, so that we employed the lowest concentration that completely inhibited the target pathway (data not shown).

To explore the role of the PI3K pathway further we compared the IgE-induced adhesion of SHIP+/+ and -/- BMMCs to FN since SHIP-/- BMMCs have been shown to have elevated PI\(P_3\) levels\(^{29}\). Specifically, we carried out dose response (Fig 3B) and time course (Fig 3C) studies using SHIP+/+ and -/- BMMCs and found that the SHIP-/- BMMCs displayed an increased IgE-mediated adhesion at suboptimal IgE concentrations and a more rapid IgE-mediated adhesion than the SHIP+/+ cells. This was also seen when these two cell types were stimulated with SF (Figs 3B & C). Consistent with this we found that low concentrations of LY294002 delayed IgE-induced adhesion of SHIP+/+ BMMCs to FN (data not shown). Since the cell surface expression of VLA-5 was comparable on SHIP+/+ and -/- BMMCs (data not shown), the increased adhesion of SHIP-/- BMMCs suggests that SHIP plays a role in restraining the increase in VLA-5 avidity.
We then asked if the Erk or p38 pathways were playing a role in IgE-induced adhesion to FN since they are more active in IgE+Ag-induced SHIP-/- BMMCs. Specifically, we tested the MEK inhibitors, U0126 and PD98059, and the p38 inhibitor, SB203580, using concentrations that totally blocked IgE- or SF-induced Erk and p38 phosphorylation. As can be seen in Fig 3D, these inhibitors had no effect on either IgE- or SF-induced adhesion of BMMCs to FN.

**IgE, but not SF, requires entry of extracellular calcium for BMMC adhesion to FN**

Since the binding of calcium to the extracellular domain of the VLA-5 dimer has been shown to be essential for integrin-mediated adhesion induced via inside-out signalling, we next asked if extracellular calcium (Ca\textsuperscript{++}) was also required for IgE-triggered BMMC adhesion to FN. Specifically, IgE alone or SF was added to BMMCs and adhesion to FN monitored in the presence and absence of calcium in the medium. As shown in Fig 4A, both agonists required Ca\textsuperscript{++} to trigger adhesion (as did IgE+Ag, data not shown). This confirms and extends previous reports showing that Ca\textsuperscript{++} is critical for the SF- and IgE+Ag-induced increase in the avidity of VLA-5. However, complicating the interpretation of these findings is the fact that Ca\textsuperscript{++} can also enter the cell to enhance classical PKC activity as well as other calcium dependent processes in the cell. To determine whether the entry of Ca\textsuperscript{++}, which we have shown previously occurs in response to IgE alone, is required for IgE-mediated adhesion we tested the calcium channel blocker, 2-APB. This blocker has been shown previously, at the levels we used, to reduce IgE+Ag-induced calcium entry into RBL-2H3 cells. As shown in Fig 4B, 2-APB partially reduced Ca\textsuperscript{++} entry into cells stimulated with either IgE alone or SF (or IgE+Ag, data not shown). However, while IgE-induced adhesion to FN (as well as IgE+Ag induced...
adhesion, data not shown) was reduced in the presence of 2-APB, SF-induced adhesion was not (Fig 4C). Thus IgE, but not SF, may require an influx of Ca\textsuperscript{++} to increase the avidity of VLA-5 on BMMCs.

To confirm the role of Ca\textsuperscript{++} entry in IgE-induced, but not SF-induced, adhesion we utilized BMMCs from Lyn+/+ and -/- mice. As shown in Fig 5A, we did not observe any calcium influx into Lyn-/- BMMCs in response to IgE, SF or IgE+Ag while responses were normal with Lyn+/+ BMMCs. This corroborates and expands on the very recent findings that IgE+Ag-induced calcium influx is dependent on the presence of Lyn in BMMCs\textsuperscript{34} and that SF-induced calcium entry is dependent on a Src family kinase\textsuperscript{35}. We then compared the ability of IgE, IgE+Ag and SF to induce the adhesion of Lyn+/+ and -/- BMMCs to FN and found, as predicted from our 2-APB results, that IgE- and IgE+Ag-induced adhesion to FN was significantly lower with Lyn-/- than with Lyn+/+ BMMCs (Fig 5B). Also in support of our 2-APB findings, the impaired Ca\textsuperscript{++} entry in the absence of Lyn did not reduce SF-induced adhesion of these BMMCs to FN. In fact we reproducibly observed a slight increase in SF-induced adhesion with Lyn-/- BMMCs (Fig 5B). It is worthy of note that the cell surface Fc\textsubscript{e}RI and c-kit levels were similar on Lyn +/+ and -/- BMMCs (data not shown).

To explore the signalling requirements for IgE-induced adhesion further we tested the phospholipase C\textsubscript{y} (PLC\textsubscript{y}) inhibitor, U73122. PLC\textsubscript{y} cleaves PI-4,5-P\textsubscript{2} to generate two second messengers; diacylglycerol (DAG), which binds and activates a subset of PKC family members\textsuperscript{36} and IP\textsubscript{3}, which binds to IP\textsubscript{3} receptors on endoplasmic reticula and mitochondria to release intracellular stores of calcium\textsuperscript{33}. This release in turn triggers the entry of Ca\textsuperscript{++} and the
subsequent activation of many calcium-dependent processes. As can be seen in Fig 6A, U73122 but not its inactive analog, U73343, markedly inhibited both IgE-induced and SF-induced adhesion of BMMCs to FN. The 1 µM concentration used was shown to block both intracellular calcium release and subsequent Ca\textsuperscript{2+} entry (data not shown). This suggested that DAG and/or IP\textsubscript{3} (ie, Ca\textsubscript{2+} entry) were required for IgE-induced adhesion and that DAG was required for SF-induced adhesion (since Ca\textsubscript{2+} entry had been ruled out as necessary in the previous experiment).

To probe the role of DAG and calcium further we asked if one or more of the 12 isoforms of PKC might be involved since both calcium and DAG are known activators of certain PKCs\textsuperscript{36}. To test this we first added the pan-specific PKC inhibitor, Compound 3 (bisindolylmaleimide I) to our adhesion assay. As shown in Fig 6B, no inhibition was observed with various concentrations of Compound 3, including 25 µM, which completely blocked IgE+Ag-induced phosphorylation of I kB at Ser\textsuperscript{32}\textsuperscript{30}. In fact a modest stimulation was consistently observed, both in the absence and presence of IgE alone or SF. This is consistent with a previous report demonstrating that Compound 3 did not inhibit SF-induced adhesion of BMMCs\textsuperscript{37}. Thus it is likely that one or more isoforms of PKC may actually play a negative role in regulating the avidity of VLA-5 on BMMCs for FN. We then tested the classical PKC inhibitor, Gö6976, at various concentrations and found, consistent with the 2-APB results described above, that it potently inhibited IgE-induced (and IgE+Ag-induced) but not SF-induced adhesion to FN (Fig 6C). This suggested that a calcium-dependent PKC may positively regulate IgE- but not SF-induced adhesion. Alternatively, Gö6976 may be acting through a different kinase to inhibit IgE-induced adhesion.
VLA-5 activation acts together with IgE to prolong intracellular signalling and enhance cytokine production and BMMC survival

To investigate the downstream ramifications of IgE-induced adhesion of BMMCs to FN we first asked if there were any apparent differences in intracellular signalling events when cells were stimulated with IgE alone versus IgE+FN (ie, do IgE-induced adherent BMMCs display a different signalling pattern because of input from the activated VLA-5?). To test this we first compared the overall tyrosine phosphorylation pattern of BMMCs in suspension versus attached to FN, at different exposure times to IgE. As can be seen in Fig 7A (top panel), tyrosine phosphorylation was substantially prolonged with FN-adherent cells. We then carried out similar time course studies to specifically examine the effect of IgE alone versus IgE+FN on Erk 1 and 2 phosphorylation and found that phosphorylation was both prolonged and more intense when the cells were attached to FN (Fig 7A, middle panel). A reprobe with anti-Erk antibodies demonstrated equal loading (Fig 7A, bottom panel).

To look at the biological ramifications of IgE-induced adhesion to FN we asked if IgE alone, which does not trigger detectable degranulation in suspension cultures of BMMCs, might now trigger degranulation of FN-adhered cells. However, no significant degranulation was observed (data not shown). We then compared the levels of pro-inflammatory cytokines secreted into the medium from non-adherent versus FN-adherent IgE-treated BMMCs. For these experiments, BMMCs were stimulated with 5 µg/ml IgE for 3 h in the presence of 15µ polystyrene beads previously coated with BSA or FN. IL-6 and TNFα ELISAs revealed that IgE-induced activation of VLA-5 substantially increased the levels of these cytokines (Fig 7B).
Since we had previously shown that the production of autocrine-acting cytokines may contribute to IgE-mediated enhancement of BMMC survival, we next performed survival studies with IgE in the presence and absence of FN. Two concentrations of IgE were initially tested, 2 µg/ml and 5 µg/ml, and viable cells were counted after 4 days. We observed, as seen in Fig 7C (left panel), that adhesion to FN significantly enhanced this IgE-mediated survival, and this enhancement appeared to be greatest at suboptimal concentrations of IgE. Even after 1 week in the presence of 2 µg/ml IgE, for example, IgE-induced binding to FN consistently enhanced BMMC survival approximately two-fold (Fig 7C, right panel).
Discussion

Mast cells congregate in connective tissue and are especially numerous beneath the epithelial surfaces of the skin and in the respiratory, gastrointestinal and genito-urinary tracts. This tissue localization, which plays a critical role in enabling mast cells to respond rapidly to invading parasites, bacteria and environmental antigens, is thought to involve the binding of mast cell progenitors via their integrins to connective tissue components. We demonstrate herein that IgE alone (at approximately 2 µg/ml), is capable of maximally triggering adhesion of both BMMCs and CTMCs to FN and does so to the same extent as optimal levels of SF (approximately 10 ng/ml) or IgE+Ag (5 ng/ml of Ag). Interestingly, these levels of SF and Ag are substantially lower than those required to induce BMMC proliferation and degranulation, respectively, confirming earlier reports \(^\text{11,12,23}\) and may suggest that, in vivo, low levels of these stimuli play an important role in mast cell recruitment. Relevant to this, the concentration of SF in normal human serum is approximately 3 ng/ml \(^\text{38}\) while that of IgE ranges from less than 0.1 µg/ml in normal individuals to more than 30 µg/ml in highly atopic individuals \(^\text{39}\). Thus it is possible that IgE alone only plays a significant role in mediating recruitment, adhesion and subsequent cytokine production and survival of mast cells during infections or allergic reactions.

The ability of IgE alone to enhance BMMC survival was recently published back-to-back by our group \(^\text{16}\) and Asai et al \(^\text{40}\). However, while Asai et al contend that this IgE-induced survival does not involve intracellular signalling, our data strongly implicate signalling. In fact, more recent studies in our laboratory reveal that all IgEs studied to date (including SPE-7, anti-Epo26, and the Liu anti-DNP IgE) can trigger signalling, albeit to different degrees, in normal BMMCs and the ability of a particular IgE to induce signalling correlates with its ability to promote survival
(Kalesnikoff et al, manuscript in preparation). Importantly, we have found in the current study that, regardless of the IgE used, adhesion can be blocked using intracellular signalling inhibitors (data not shown).

Taken together, our inside-out signalling studies suggest that the activation of both the PI3K pathway and the PLCγ-generated IP₃ pathway (and subsequent draining of intracellular calcium stores, Ca_o⁺⁺ entry and perhaps activation of one or more classical PKCs) are critical to IgE-mediated (and IgE+Ag-mediated) adhesion. SF-mediated adhesion, on the other hand, appears to be independent of Ca_o⁺⁺ entry but dependent on the activation of both the PI3K pathway and PLCγ-generated DAG (and thus may be positively regulated by one or more calcium independent, DAG-dependent PKCs) (see model in Fig 8). Of interest, Toker et al have shown that PKCε is the PKC that is most activated by PIP₃ in vitro 36 making it a good candidate for mediating SF-induced adhesion. Alternatively, SF-induced production of DAG may lead to an increase in VLA-5 avidity via the activation of other proteins, such as Ras or Rap1 via activation of RasGRPs 41, since we and Dastych et al37 found that SF-stimulated adhesion of BMMCs to FN is unaffected by Compound 3. Specific PKC-/- BMMCs may be useful in resolving this issue.

Our results are consistent with earlier studies showing that the PI3K pathway plays a critical role in SF- and IgE+Ag-induced adhesion of BMMCs to FN 22,27,37. Intriguingly, Kinashi et al 22 found that BMMC adhesion to FN could be triggered via a constitutively active PI3K but not a constitutively active Akt/PKB, suggesting that elevated PIP₃ but not the downstream Akt pathway is critical to inside-out signalling. Although Vosseller et al 28 concluded that a calcium-
independent, PIP$_3$-dependent PKC might be involved in SF-mediated adhesion to FN, they did not observe calcium entry in response to SF. In keeping with our results, however, Ueda et al. $^{35}$ recently reported that SF does induce calcium entry in c-kit transfected Ba/F3 cells and that Lyn is a key mediator of this influx. Also relevant to our model, Lorentz et al. $^{42}$ very recently reported that SF-stimulated adhesion of human intestinal mucosa derived mast cells to FN is blocked with 100 nM wortmannin or 20 µM apigenin but not with 2 µM Gö6976. Apart from their results with apigenin, a putative Erk pathway inhibitor, this is in agreement with our SF findings. Our results with the MEK inhibitors, PD98059 and U0126, suggest that IgE-, SF- and IgE+Ag-induced adhesion does not require the Erk pathway. Moreover, we found that apigenin is not a specific Erk pathway inhibitor. In fact, it inhibits many pathways at 20 µM, including the SF-induced tyrosine phosphorylation of c-kit, while at 5 µM it inhibits neither Erk phosphorylation nor SF-induced adhesion (data not shown).

The role that Ca$^{2+}$ plays in mast cell adhesion is complicated because it not only binds directly to the extracellular domains of the integrins to modulate heterodimer formation and affinity for FN and other ligands but it can also enter the mast cell to activate various intracellular pathways $^{15,24,31,33}$. As far as the latter is concerned, it has been known for some time that intracellular calcium is involved in the inside-out signalling that leads to integrin-mediated adhesion and recent studies with LFA-1 mediated adhesion to ICAM-1 suggest, perhaps, a general role for intracellular calcium in increasing the avidity of integrins by activating the calcium-dependent protease, calpain. This protease then cleaves the attachment between the integrin and the cytoskeleton, allowing the integrin to move in the membrane and gather in clusters $^{31}$. One major
question that arises from our data is how SF, which does not appear to require entry of Ca\textsubscript{o}\textsuperscript{++} to increase adhesion, mediates integrin clustering.

Engagement of integrins by their ligands is known to activate various signalling pathways and this is referred to as "outside-in" signalling. These "outside-in" signals have been shown to modulate signals coming in from other receptors and alter biological responses triggered by these other receptors.\textsuperscript{43} Our observation that tyrosine phosphorylation events are prolonged and of greater intensity when VLA-5 activation acts in concert with IgE stimulation is reminiscent of earlier studies by Hamawy et al\textsuperscript{44} who showed that Fc\varepsilon RI aggregation-induced adhesion of RBL-2H3 cells to FN increased the tyrosine phosphorylation of FAK. Furthermore, the enhanced inflammatory cytokine production that we observe with IgE-induced adhesion is somewhat consistent with earlier studies showing that adhesion of mast cells to FN via VLA-5 enhances IgE+Ag-induced degranulation\textsuperscript{13,23} and release of inflammatory cytokines\textsuperscript{13}. Interestingly, the enhanced IgE-induced survival we observe with FN-bound BMMCs may explain, at least in part, the elevated mast cell numbers seen in atopic individuals with elevated plasma IgE levels. Related to this, Ra et al found that the IgE+Ag-induced adhesion of rat and mouse cultured mast cells to FN led to greater survival (perhaps via the autocrine action of IL-3) than with IgE+Ag alone\textsuperscript{13}. In addition, it is conceivable that the ability of IgE to induce cytokine production could play a role in IgE-induced adhesion. Coward et al\textsuperscript{45}, for example, recently showed that TNF\textalpha acts as a positive autocrine signal to augment NFkB activity in human lung mast cells, making it a good candidate for the induction of adhesion in a feedback loop. On the other hand, Lorentz et al\textsuperscript{42} found that TNF\textalpha, NGF, IFN\gamma, TGF\beta, IL-6, IL-8, IL-10 or IL-13 did not stimulate the adhesion of human intestinal mast cells to FN. As well, apart from pre-formed TNF\textalpha, it is
unlikely that IgE-induced cytokine production is rapid enough to contribute significantly to the initial increase in adhesion triggered by IgE. However, it is conceivable that IgE-induced cytokines play a role in IgE-induced adhesion at later time points and we are currently testing this possibility.

Our findings increase the repertoire of biological effects elicited by IgE alone and raise the possibility that IgE, in the absence of Ag, may help in vivo to concentrate mast cells at sites of inflammation and promote, in concert with FN, inflammatory cytokine release and mast cell survival.
Acknowledgements

We would like to thank Christine Kelly for typing the manuscript. Lyn -/- mice were a generous gift from Dr. Cliff Lowell, UCSF.

Abbreviations: Ag, antigen; 2-APB, 2-aminoethoxydiphenyl borate; BMMCs, bone marrow derived mast cells; Ca\textsubscript{o}++, extracellular calcium; CTMCs, connective tissue mast cells; FN, fibronectin; PI3K, phosphatidylinositol 3-kinase; PLC\textsubscript{γ}, phospholipase C \textsubscript{γ}; SF, Steel Factor; VLA-5, very late antigen 5.

Fig 1. IgE alone stimulates the adhesion of both BMMCs and CTMCs to FN. (A) Adhesion of normal BMMCs to FN following a 60 min adhesion assay with increasing concentrations of IgE alone (SPE-7, top left panel; Liu anti-DNP or anti-Epo26, top right panel), SF (bottom left panel), or IgE+DNP-HSA (bottom right panel). The black bars in the top left panel indicate the level of adhesion to wells coated with BSA instead of FN. (B) A time course of BMMC adhesion to FN in the presence of 1 µg/ml IgE alone (●), 5 ng/ml SF (△), or IgE+2 ng/ml DNP-HSA (□). Background adhesion (2-6%) was subtracted from each time point. (C) Adhesion of normal CTMCs to FN in response to IgE at the indicated concentrations, 5 ng/ml SF, or IgE+5 ng/ml DNP-HSA for 60 min. Results shown are the mean ± SEM of triplicate determinations. Similar results were obtained in 5 (A), 3 (B), and 2 (C) separate experiments. Adhesion in response to all stimuli was significantly (p<0.05) different from control values except for (C) 0.1 µg/ml.
Fig 2. IgE alone stimulates the adhesion of BMMCs to FN via an increase in the avidity of VLA-5. (A) Adhesion of normal BMMCs to FN in response to assay medium alone (C), 1 µg/ml IgE, or 5 ng/ml SF in the absence (square) or presence of 400 µg/ml RGD-containing peptide (square) or 400 µg/ml control RGE-containing peptide (square) for 15 min. Adhesion in response to IgE and IgE+RGE peptide, but not IgE+RGD peptide, was significantly (p<0.05) different from control values. (B) Adhesion of BMMCs to FN in response to assay medium alone (C), 0.5 µg/ml IgE, or 5 ng/ml SF for 15 min in the absence (square) or presence (square) of 40 µg/ml anti-CD49e added 30 min prior to stimulation. Adhesion was significantly (p<0.05) different between control (C) and all stimulated samples as well as between stimulated and stimulated + anti-CD49e treated samples. Results shown are the mean ± SEM of triplicate determinations and similar results were obtained in 3 (A) and 3 (B) separate experiments. BMMCs were incubated on (C) BSA for 1 h or
(D) BSA for 4 h (top panel) or on FN for 4 h (bottom panel) in the absence (—) or presence (---) of 2 µg/ml IgE. The cells were then stained with anti-CD49e antibody (1 µg/5x10^5 cells) for 30 min at 4°C and analyzed by FACS. The blackened area profiles were obtained with isotype control antibody.
Fig 3. IgE-induced adhesion of BMMCs to FN requires PI3K but not Erk or p38. (A)

Adhesion of normal BMMCs to FN in response to 1 µg/ml IgE or 5 ng/ml SF in the presence of the indicated concentrations of LY294002 (LY) following a 30 min adhesion assay. All wells contained the same level of DMSO (vehicle for LY). Adhesion was significantly (p<0.05) different between control stimulated and stimulated +LY294002 treated samples. (B) Adhesion of SHIP+/+ (■) and -/- (□) BMMCs to FN following a 60 min exposure to the indicated concentrations of IgE or SF. Adhesion was significantly (p<0.05) different between SHIP+/+ and -/- levels except for the control, 0.1 and 5 µg/ml values. (C) A time course of the adhesion of SHIP+/+ (■) and -/- (□) BMMCs to FN in the presence of 1 µg/ml IgE and, for comparison, a 60 min exposure to 0.5 ng/ml SF. Adhesion was significantly (p<0.05) different between SHIP+/+ and -/- values. (D) Adhesion of normal BMMCs to FN for 30 min in the presence of 1 µg/ml IgE (■) or 2 ng/ml SF (□) in the absence (C) or presence of 1 µM U0126, 20 µM
PD98059 (PD), or 10 µM SB203580 (SB). All wells contained the same level of DMSO (vehicle for the inhibitors). Adhesion was not significantly different between IgE- and IgE+U0126-, PD98059- or SB203580-stimulated samples. Results shown are the mean ± SEM of triplicate determinations. Background adhesion was subtracted from the values graphed in (A, 14%), (C, 4-11%), and (D, 5-11%). Similar results were obtained in 4 (A), 5 (B), 3 (C), and 3 (D) separate experiments.
Fig 4. IgE, but not SF, requires the entry of extracellular calcium to trigger BMMC adhesion to FN. (A) Adhesion of normal BMMCs to FN in response to medium alone (C), 1 µg/ml IgE, or 5 ng/ml SF for 30 min with (■) or without (□) the addition of 1.8 mM CaCl₂. (B) Intracellular calcium measurements in BMMCs stimulated with 5 µg/ml IgE (—; left panel) or 50 ng/ml SF (—; right panel) alone, or in the presence of 50 µM 2-APB (---) or 5 mM EGTA (—). The 2-APB was pre-incubated with the cells for 30 min while the EGTA was added immediately prior to the addition of IgE or SF at 100 s (↓). (C) Adhesion of BMMCs to FN in response to 1 µg/ml IgE or 5 ng/ml SF for 30 min in the presence of vehicle control (□), 25 µM (■), or 50 µM (☑) 2-APB added 30 min prior to stimulation. The background adhesion (6%) was subtracted. Adhesion was significantly (p<0.05) different between IgE- and IgE+2-APB-stimulated, but not SF- and SF+2-APB-stimulated samples. Results shown are the mean ± SEM.
of triplicate determinations. Similar results were obtained in 3 (A), 3 (B), and 3 (C) separate experiments.
Fig 5. Lyn -/- BMMCs, which do not show increased intracellular calcium with IgE, SF, or IgE+Ag, display impaired adhesion to FN in response to IgE or IgE+Ag but not to SF. (A) Intracellular calcium measurements in Lyn +/+ (—) and -/- (---) BMMCs in response to 10 µg/ml IgE (left panel), 100 ng/ml SF (middle panel), or IgE+20 ng/ml DNP-HSA (right panel) injected at 100 s (↓). (B) Adhesion of Lyn +/+ (■) and -/- (□) BMMCs to FN following a 60 min exposure of the cells to the indicated concentrations of IgE, SF, or IgE+DNP-HSA. The background adhesion (8-15%) was subtracted. Adhesion was significantly (p<0.05) different between Lyn+/+ and -/- BMMCs except for 0.5, 1 ng/ml SF and 0.1, 0.5, 1 ng/ml DNP-HSA. Results shown are the mean ± SEM of triplicate determinations. Similar results were obtained in 3 (A) and 3 (B) separate experiments.
Fig 6. IgE, but not SF, may require a calcium dependent PKC to trigger BMMC adhesion to FN. (A) Adhesion of normal BMMCs to FN in response to 1 µg/ml IgE or 5 ng/ml SF in the presence of vehicle control ( ), 1 µM U73122 ( ), or 1 µM U73343 ( ). Adhesion was significantly (p<0.05) different between stimulated samples in the presence and absence of U73122 but not U73343. (B) Adhesion of BMMCs to FN in response to 1 µg/ml IgE or 5 ng/ml SF in the presence of the indicated concentrations of Compound 3 (C3). Adhesion was significantly (p<0.05) different between stimulated samples in the presence and absence of C3 at 25 and 50 µM C3 (C) Adhesion of BMMCs to FN in response to 1 µg/ml IgE or 5 ng/ml SF in the presence of the indicated concentrations of Gö6976 (Gö). Adhesion was significantly (p<0.05) different between IgE- but not SF-stimulated samples in the presence and absence of...
Gö. All adhesion assays were 30 min and the results shown are the mean ± SEM of triplicate determinations. Background adhesions (A, 4%, B, 13% & C, 4%) were subtracted. Similar results were obtained in 4 (A), 4 (B), and 3 (C) separate experiments.
Fig 7. FN binding enhances IgE-induced intracellular signalling events, cytokine production, and survival. (A) Total cell lysates (50 µg as assessed by BCA assays) from IgE-stimulated suspension and FN-adhered BMMCs were subjected to Western analysis using anti-phosphotyrosine antibodies (4G10) (top panel) or anti-phospho-specific Erk antibodies (middle panel) and reprobed with anti-Erk antibodies (bottom panel) to demonstrate equal loading. (B) BMMCs were stimulated for 3 h at the indicated concentrations of IgE in the presence of 15 µ polystyrene beads coated with BSA (□) or FN (■). IL-6 (left panel) and TNF-α (right panel) levels in the supernatants were detected by ELISA. (C) BMMCs were plated at 5x10^5 cells/ml in IMDM + 0.1% BSA ± IgE at 2 and 5 µg/ml in FN (■) or BSA (□) coated wells. On day 4, viable cells were counted by trypan blue exclusion (left panel). In the right panel, BMMCs were set up as above ± 2 µg/ml IgE and viable cells counted on day 7. Data points are the mean ± SEM of 6 (B), 2 (C left) and 3 (C right) determinations. Similar results were obtained in 3 (A), 4 (B), and 3 (C) separate experiments.
Fig 8. A model of IgE-induced adhesion to FN. IgE binding to the FccR1 on BMMCs allows them to aggregate at a low frequency. This results in a relatively low (compared to IgE+Ag) but prolonged signal that activates, among other pathways, the PI3K and PLCγ pathways. These 2 pathways play a critical role in IgE- and IgE+Ag-induced adhesion to FN by inducing the entry of extracellular calcium and the activation of a classical PKC. SF-induced adhesion of BMMCS to FN, on the other hand, appears to require the stimulation of the PI3K and PLCγ pathways and the subsequent critical activation of a novel (DAG-dependent, calcium independent) PKC.
IgE alone stimulates mast cell adhesion to fibronectin via pathways similar to those used by IgE+ antigen but distinct from those used by Steel Factor
