ABSTRACT

Engagement of B cell antigen receptor (BCR) activates kinases of the Src and Syk families and signaling complexes assembled by adaptor proteins, which dictate B cell fate and function. The adaptor 3BP2/SH3BP2, an Abl SH3-binding and Syk-kinases interacting protein, exhibits positive regulatory roles in T, NK and basophilic cells. However, its involvement in BCR signaling is completely unknown. Here we show that 3BP2 is tyrosine phosphorylated following BCR aggregation on B lymphoma cells, and that 3BP2 is a substrate for Syk and Fyn, but not Btk. To further explore the function of 3BP2 in B cells, we screened a yeast two-hybrid B lymphocyte library and found 3BP2 as a binding partner of Vav proteins. The interaction between 3BP2 and Vav proteins involved both constitutive and inducible mechanisms. 3BP2 also interacted with other components of BCR signaling pathway, including Syk and PLC-γ. Furthermore, overexpression and RNAi blocking experiments showed that 3BP2 regulated BCR-mediated nuclear factor of activated T cells (NFAT) activation. Finally, evidence was provided that 3BP2 functionally cooperates with Vav proteins and Rho GTPases to activate NFAT. Our results show that 3BP2 may regulate BCR-mediated gene activation through Vav proteins.
**Introduction**

B cell antigen receptor (BCR) engagement triggers multiple signal transduction events regulating B cell development and function. The BCR signals through conserved immunoreceptor tyrosine-based activation motifs (ITAMs) found within the cytoplasmic tails of its subunits. Ligation by antigen results in the activation of associated cytoplasmic protein tyrosine kinases (PTKs), including Syk, the Src-family PTKs Lyn and Fyn, and Btk. The activated Lyn and Fyn kinases phosphorylate the ITAMs within the Ig-α and Ig-β chains, resulting in the recruitment and activation of Syk. As a result, molecular scaffolds composed of adaptor proteins and key enzymes, such as phospholipase C-γ (PLC-γ), phosphatidylinositol 3-kinase (PI3K), and guanine nucleotide exchange factors (GEFs) Vav1 and Vav2, are assembled and activated at the plasma membrane by Src and/or Syk PTKs. These scaffolds transduce signals to the cytoplasm and nucleus to activate gene expression and metabolic changes involved in B cell homeostasis.

One critical pathway stimulated by BCR triggers intracytoplasmic calcium movements leading to the activation of transcription factors, such as nuclear factor of activated T cells (NFAT). These nuclear factors coordinate the expression of cytokines and cell cycle proteins involved in B cell growth and apoptosis. Calcium signals are triggered by activated PLC-γ that produces inositol-1,4,5-triphosphate (IP3) followed by an increase of cytoplasmic calcium. The regulation of PLC-γ activity involves the membrane translocation and activation of Btk following PI3K-mediated production of phosphatidylinositol-3,4,5-triphosphate (PIP3). Vav proteins also participate in the regulation of calcium signals and NFAT activation in lymphocytes. Vav proteins are activators of Rho family GTPases that control cytoskeletal reorganization and gene activation. Analysis of Vav1 and Vav2 deficient mice showed the importance of these proteins in BCR signaling during both development, maturation, and proliferation of B cells. The major defect in vav1-/ x vav2-/- B cells stimulated through antigen receptor appears to be a defect in calcium release. Although the basis for this defect is still unclear, it likely involves defects in PI3K, PLC-γ, and Tec-family kinases activation,
since this phenomenon has been observed in Vav1 deficient T and mast cells \(^ {12,13}\). Moreover, Vav3 has been shown to regulate PI3K activation in the DT40 chicken B cell line \(^ {14}\).

The assembly of signaling complexes is regulated by adaptor proteins that mediate protein-protein or protein-lipid interactions \(^ {15}\). In B cells, one such adaptor is the Syk substrate BLNK/SLP-65 that connects BCR to PLC-\(\gamma\) activation by providing docking sites for Btk and PLC-\(\gamma\) \(^ {2}\). In a screen for Syk-kinases interacting proteins, we previously identified 3BP2 \(^ {18}\), a cytoplasmic adaptor originally identified as a Abl SH3 domain binding protein \(^ {19}\). 3BP2 (also known as SH3BP2) is preferentially expressed in hematopoietic tissues \(^ {18,20}\), and positively regulates the activity of the transcription factors NFAT and AP-1 in T cells through calcineurin and Ras dependent pathways \(^ {18}\). A positive regulatory role of 3BP2 in NK cell-mediated cytotoxicity \(^ {21}\) and in the degranulation of rat basophilic leukemia cells \(^ {22}\) have also been described. Several cell signaling partners of 3BP2 have been described including Fyn, Zap-70, LAT, and PLC\(\gamma\) in T cells \(^ {18}\), Vav1 and PLC-\(\gamma\) in NK cells \(^ {21}\), LAT and Lyn in basophilic cells \(^ {22,23}\). A regulation of 3BP2 adaptor function by the chaperon protein 14-3-3 has also been reported \(^ {24}\). Finally, mutations in the \textit{3bp2/sh3bp2} gene were identified to cause a human bone disease called cherubism \(^ {25}\). Altogether these observations suggest that 3BP2 plays a crucial role in PTK-dependent signaling pathways during hematopoietic cells differentiation and function.

In this study, we have investigated the role of 3BP2 in BCR signaling. Using 3BP2 as a bait in a yeast two-hybrid system, we found that 3BP2 interacted with members of the Vav family of Rho GTPases activators. A combination of biochemical techniques, overexpression and RNAi blocking experiments showed that 3BP2 cooperated with Vav proteins to control a Rho GTPases-dependent pathway regulating NFAT activation in B cells. Together, our results provide the first evidence that 3BP2 is an active and important component of BCR signaling.

Methods

Reagents and antibodies
Culture media, oligonucleotides, and enzymes were from Invitrogen (The Netherlands). Chemicals were obtained from Sigma (St. Louis, MO). Polyclonal antibodies against 3BP2 were prepared following rabbit immunization with the GST 3BP2 SH2 domain fusion protein. Anti-hemagglutinin (HA; 12CA5) mAb was from Roche Diagnostics (Switzerland). The antibodies specific for the myc epitope (9E10), LexA, Vav1 and c-Cbl were from Upstate Biotechnology Inc. (Lake Placid, NY). The antibodies against Syk, ERK2, PLCγ1 and GST were from Santa Cruz Biotechnology (Santa Cruz, CA). Anti-phosphotyrosine mAb were purified from culture supernatants of the corresponding hybridoma by protein A-Sepharose chromatography. The anti-human Vav2 mAb was a gift from J. Downward (London, UK). F(ab’)2 fragments of anti-human IgM were from Dako (Denmark).

**Plasmids**

Plasmid construction, cloning and DNA sequencing were carried out according to standard protocols. The yeast expression plasmids pLex9, pACTII, and the HA-tagged 3BP2 constructs in the expression vector pMT3, and 3BP2 constructs in the yeast expression vector pLex9 were described before. The NFAT luciferase reporter construct was from G. Crabtree (Stanford, CA). Plasmids encoding myc-tagged Vav1 and Vav2, GST-Vav2 SH3-SH2-SH3, GST-3BP2 SH2 and HA-Rac1 were previously described.

**Cell culture and transfection**

The human B (BJAB, RPMI8866, Daudi and Raji) and T (Jurkat) cell lines were obtained from the American Type Culture Collection (ATCC; Manassas, VA). Cells were grown in RPMI 1640 medium (Invitrogen), supplemented with 10% fetal calf serum (FCS; Dutcher, Brumath, France), 2 mM glutamine, 1 mM sodium pyruvate, 10 mM HEPES, non-essential amino acids solution, and 100 units/ml of penicillin and streptomycin. Cells grown in a logarithmic growth phase were transfected with the indicated amounts of plasmids by electroporation using the Gene Pulser (Bio-Rad Laboratories). Simian COS-1 were cultured in Dulbecco modified Eagle's medium (Invitrogen) with 10% FCS. 1x10^7 cells were plated the
day before transfection. Transfections were then performed by calcium phosphate precipitation.

**Yeast Two-Hybrid System**

Growth and transformation of the yeast strain L40 were performed as described before. Briefly, a human B lymphocyte cDNA library encoded by the yeast two-hybrid vector pACTII was transformed into yeast cells that were previously transformed by the pLex9 3BP2 bait vector. Transformed cells were plated on synthetic drop-out medium lacking tryptophan, leucine, histidine, and uracil, and grown for 4 days at 30°C. Colonies were then assayed for β-galactosidase activity using a filter assay. After a second round of screening performed with a LexA-lamin plasmid as a negative control, library plasmid cDNAs were rescued, sequenced, and identified using the BLAST algorithm.

**GST pulldown assays**

GST fusion proteins were expressed in BL21 bacteria with 1 mM isopropyl-β-D-thiogalactopyranoside (IPTG) for 3 h at 37°C. Proteins were affinity purified using glutathione-Sepharose beads. Purified proteins were resolved by SDS-PAGE, and analyzed by Coomassie staining. For GST precipitations, cells were lysed at 1x10^8 cells/ml in ice-cold lysis buffer (1% Nonidet P-40 in 150 mM NaCl, 50 mM HEPES [pH 7.4], 5 mM NaF, 5 mM sodium pyrophosphate, 1 mM sodium orthovanadate, 10 μg/ml aprotinin, 10 μg/ml leupeptin, 1 mM PMSF) for 30 min on ice. Lysates were clarified by centrifugation at 15,000 x g for 15 min at 4°C, and incubated with 10 μg of the indicated GST fusion protein and glutathione-Sepharose beads (Sigma) for 3 h at 4°C. After extensive washing in lysis buffer, bound proteins were detected by immunoblotting as indicated below.

**Immunoprecipitation and immunoblotting**

Cells were lysed at 1x10^8 cells/ml in ice-cold lysis buffer for 30 min on ice. In some experiments, cells were lysed in membrane rafts-solubilizing buffer (1% Octylglucoside in
IMMUNOBIOLOGY

140 mM NaCl, 10 mM TRIS-HCl [pH 8.0], 1 mM EDTA, 1 mM NaF, 1 mM sodium orthovanadate, 10% glycerol, 10 μg/ml aprotinin, 10 μg/ml leupeptin, 1 mM PMSF for the same period of time. Cleared lysates were then incubated for 3 h at 4°C with the indicated antibodies and 1 h with protein G-Sepharose beads (Sigma). Pellets were then washed three times with ice-cold lysis buffer and resuspended in SDS sample buffer. Eluted immunoprecipitates or whole-cell lysates were separated by SDS-PAGE, and analyzed by immunoblotting. SDS-PAGE-resolved samples were transferred to nitrocellulose membranes, and probed with primary and horseradish peroxidase (HRP)-conjugated secondary antibodies followed by enhanced chemiluminescence detection (ECL).

Reporter assays

Cells were transiently transfected with NFAT reporter plasmid along with the indicated expression plasmids, and a control Renilla luciferase plasmid vector (pRL-TK) for normalization of transfection efficiency (Promega). After 18h, cells were washed and stimulated or not with anti-IgM (2 μg/ml), or a combination of PMA and ionomycin for 6h at 37°C. Luciferase activities were determined using the Dual Luciferase Reporter Assay System (Promega) according to the manufacturer's instructions. Normalized Firefly luciferase activities (NFAT) were expressed as fold increase relative to the basal activity seen in unstimulated mock-transfected cells.

RNA interference

Synthetic siRNA oligonucleotides were synthesized and purified by Dharmacon, Inc. (Lafayette, CO). siRNA against human 3BP2 was 5’-AAGAGUAGCACCUCUGCCUCC-3’ (si3BP2). The sequence of the control siRNA against green fluorescent protein (GFP) was 5’-AAGGCUACGCUCCAGGAGCGCACC-3’ (siGFP). A 5’-fluorescein-conjugated-luciferase siRNA (5’-CGUACGCGGAAUACUUCGU-3’) was used in some experiments for sorting cell populations transfected with siRNA. The efficiency of 3BP2 siRNA was examined in Jurkat (10^7) or Raji (5 10^7) cells electroporated with 2 μg of 3BP2 siRNA or control siRNA in the presence of 5’-FITC-conjugated-luciferase siRNA. After 24 h, cells were sorted by FACS,
IMMUNOBIOLOGY

lysed and 3BP2 expression was determined by immunoblotting. For determination of NFAT activity in 3BP2 knock-down cells, Raji or Jurkat cells (2 \(10^7\)) were electroporated with 2 \(\mu\)g siRNA, 15 \(\mu\)g of NFAT reporter and 3 \(\mu\)g of Renilla luciferase plasmid. After 18h, cells were washed and stimulated for 6h at 37°C. Triplicate of luciferase activities were measured and expressed as described above.

**Determination of Rac1 activity**

Rac1 activity was determined by a modification of the pull-down assay described before. Briefly, cells (2 \(10^7\)) were transfected with 5\(\mu\)g of HA-tagged Rac1 expression plasmid along with 20\(\mu\)g of either 3BP2 or Vav1 expression plasmids. 24 h after transfection, cells were lysed in Rac pull-down assay buffer (0.5% Triton X100 in 150 mM NaCl, 25 mM Tris [pH 7.5], 5 mM MgCl2, 0.5 mM EGTA, 4% glycerol, 1 mM \(\beta\)-glycerophosphate, 2 mM sodium orthovanadate, 5 mM DTT, 1 mM PMSF) for 30 min at 4°C. Clear lysates were incubated with 10 \(\mu\)g of GST-PBD fusion protein expressing the Rac1-binding domain pf p21-activated kinase 3 (Pak3) and glutathione-Sepharose beads for 45 min at 4°C. After extensive washings in lysis buffer, bound Rac1 proteins were detected by anti-HA immunoblotting. Prior to the incubation with beads, 50 \(\mu\)l aliquots were removed from samples to control the expression of total HA-Rac1 proteins.

**Results**

**3BP2 is phosphorylated following BCR stimulation**

To examine the function of 3BP2 in B cells, we first examined its expression in different B cell lines. 3BP2 was abundantly expressed in the Burkitt lymphoma cell line Daudi, and to a lesser extend in BJAB, Raji, and RPMI8866 cells (Figure 1A). The specificity of the polyclonal antibodies against 3BP2 was examined by blotting 3BP2 immunoprecipitates from lysates of Raji cells transfected with HA-tagged 3BP2 cDNA (Figure 1B). We then examined the tyrosine phosphorylation of 3BP2 following BCR engagement. 3BP2 immunoprecipitates from lysates of Daudi cells stimulated with anti-IgM antibodies were analyzed by anti-
phosphotyrosine immunobloting. Figure 1C shows that 3BP2 was tyrosine phosphorylated after BCR engagement. As an attempt to identify the kinase(s) involved in this process, HA-tagged 3BP2 was cotransfected with plasmids encoding Fyn, Syk or Btk kinases. Western blot analysis of anti-HA immunoprecipitates shows that 3BP2 is tyrosine phosphorylated by Fyn and Syk, but not by Btk in intact cells (Figure 1D), suggesting that 3BP2 may be a substrate of Src- and Syk-, but not Tec-, family kinases in BCR signaling.

Identification of Vav family members as 3BP2 interacting proteins

To identify novel partners of 3BP2 in B cells, we employed the yeast two-hybrid interaction analysis. 3BP2, fused to the DNA-binding domain of LexA, was used to screen a human B lymphocyte library. Of the clones selected for sequence analysis, one Vav1 and two Vav2 clones were identified by comparison with the nucleotide data base at the National Library of Medicine using the BLAST algorithm (Figure 2A). To confirm the interaction between 3BP2 and Vav proteins in mammalian cells, COS-1 cells were transiently cotransfected with a combination of plasmids encoding HA-tagged 3BP2, myc-tagged Vav1 and Vav2, or empty vectors. Anti-3BP2 immunoprecipitates were analyzed by western-blot using anti-myc antibody. The membranes were then stripped and 3BP2 expression was controlled by blotting with anti-HA antibody. As shown in Figure 2B, 3BP2 coimmunoprecipitated both with Vav1 and Vav2. Using a similar approach, an association between 3BP2 and Vav3 was also detected (Figure 2C). These data indicate that a constitutive complex between 3BP2 and Vav proteins exists both in yeast and in mammalian cells.

3BP2 associates Vav1 and other signaling molecules following BCR engagement

To examine the association between endogenous 3BP2 and Vav proteins in B cells, 3BP2 was immunoprecipitated from lysates of Daudi cells stimulated or not with anti-IgM antibodies. Anti-phosphotyrosine blotting analysis showed that following BCR stimulation different phosphoproteins coprecipitated with 3BP2 in resting and anti-IgM stimulated cells (Figure 3A). By reprobing membranes with antibodies against known tyrosine-phosphorylated proteins with similar molecular mass, we determined that one of these 3BP2-associated
phosphoproteins was Vav1. The interaction between 3BP2 and Vav1 was constitutive and increased following B cell activation. A similar association of 3BP2 with Vav2 was observed in Daudi cells (data not shown). The specificity of these interactions was controlled on immunoprecipitates performed with irrelevant antibodies (Figure 3A). To rule out the possibility that the 3BP2/Vav1 interaction may be indirect due to association of phospho-3BP2 with membrane lipid rafts, unstimulated Daudi cells were solubilised in a buffer containing 1% octylglucoside, and co-immunoprecipitations were performed. As shown in Figure 3B, 3BP2 specifically co-precipitated with Vav1 in detergent conditions under which lipid rafts are dissociated. Similar results were obtained in other B cell lines including Raji and Ramos (data not shown). To further characterize 3BP2/Vav interaction in B lymphocytes, in vitro GST pulldown assays were next performed. When GST Vav2 SH3-SH2-SH3 - but not GST alone - was incubated with lysates from resting or activated Daudi cells, a constitutive binding of 3BP2 was detected, in addition to an inducible binding to Syk and c-Cbl (Figure 3C). A similar approach using GST 3BP2 SH2 showed that the SH2 domain of 3BP2 bound several tyrosine phosphorylated proteins from lysates of BCR-stimulated Daudi B cells (Figure 3D). Bound proteins included important fractions of total Vav1 and PLC-γ, and a significant fraction of Syk. These interactions were not detected on GST precipitates. Together, these data indicate that 3BP2 binds critical molecules of BCR signaling, including Vav proteins.

**In vivo mapping of Vav1/2 binding domain on 3BP2**

Next, we performed co-immunoprecipitations in COS-1 cells in order to map the region of 3BP2 that binds Vav proteins. 3BP2 is composed of a N-terminal plekstrin homology (PH) domain, a central proline-rich (PR) region with three domains (PR1, PR2, PR3) containing SH3 binding consensus sequences, and a C-terminal Src homology 2 (SH2) domain. COS-1 cells were cotransfected with plasmids encoding different HA-tagged 3BP2 deletion mutants (Figure 4A), and either myc-tagged Vav1 (Figure 4B) or myc-tagged Vav2 (Figure 4C). HA-immunoprecipitates from unstimulated cells were then probed with anti-myc antibody. As shown in Figure 4B and C, the PH domain, the PR2 and PR3 regions, and the SH2 domain of
3BP2 were not required for interacting with Vav1 or Vav2. In contrast, deletion of PR1 domain (aa 201 to 240) significantly decreased the interaction between 3BP2 and Vav proteins. Interestingly, the deletion of either PR3 or SH2 domains apparently reinforced 3BP2/Vav proteins binding, suggesting a conformational regulation of this interaction. Note that identical results were obtained in yeast binding assays (data not shown). These data indicate that, in addition to a phosphotyrosine/SH2 domain dependent interaction, the first proline-rich domain of 3BP2 (PR1) also binds Vav proteins in intact cells.

3BP2 is involved in BCR-mediated activation of NFAT

In order to clarify the function of 3BP2 in BCR signaling, we first examined the effect of overexpression of the 3BP2 mutants described above on BCR-mediated NFAT activation. 3BP2 constructs were overexpressed in Daudi cells and NFAT activation was determined using luciferase assays. Figure 5A shows that deleting the SH2 domain of 3BP2 dramatically reduced both basal and anti-IgM mediated NFAT activation, whereas PR1 deletion led to approximatively 50% of diminution of NFAT activities compared to wild-type 3BP2 protein. Other functionally important domains of 3BP2 included PH and PR3 domains, whereas PR2 apparently did not participate to 3BP2-mediated NFAT activation. Overexpression of 3BP2 SH2 domain (3BP2 454-559) in Daudi B cells also decreased the activation of NFAT induced by BCR engagement (Figure 5B).

To further confirm the role of 3BP2 in BCR signaling, we used RNA interference (RNAi). Transfection efficiencies are very low in B cell lines. We therefore first tested siRNAs duplexes capable of knocking down 3BP2 expression in transfected Jurkat T cells (Figure 6A). Immunoblot analysis show that siRNA against 3BP2 specifically reduced the expression of 3BP2 protein, compared to control siRNA against GFP (right panel). Quantification of the immunoblot signals showed that 3BP2 expression was reduced up to 80% (data not shown). NFAT luciferase assays revealed that reducing 3BP2 expression in Jurkat T cells decreased TCR-mediated NFAT activation by 35 to 40% as compared to control (Figure 6A, left panel). We next transiently transfected Raji B cells with si3BP2 or siGFP oligonucleotides together with NFAT-driven luciferase reporter. The cells were stimulated or not with anti-IgM
antibodies and normalized luciferase activities were measured. As shown in Figure 6B (left panel), interfering with 3BP2 expression in B cells resulted in a significant reduction of BCR-mediated NFAT activation (20 to 25% reduction compared to control). Immunoblot analysis on the siRNA-transfected population of Raji cells show that 3BP2 expression was abrogated by si3BP2 (Figure 6B, right panel). Together with overexpression experiments, these data suggest that 3BP2 participates to BCR-mediated transcriptional activation.

**Functional cooperation between 3BP2 and Vav family proteins for Rac and NFAT activation**

Vav proteins are important regulators of Rho GTPases and NFAT activities in lymphoid cells, and we previously found that overexpression of 3BP2 leads to activation of NFAT in T cells. We thus questioned a role of 3BP2 in Rac activation and whether 3BP2/Vav proteins interaction participate to BCR-mediated NFAT activation. For the same technical limitation described above, we used Jurkat T cells to test the effect of 3BP2 overexpression on Rac1 activity using a Rac pull-down assay. Jurkat T cells were transfected with HA-tagged Rac1 together with 3BP2 or Vav1 cDNAs, then lysed and incubated with GST-PDB fusion protein and glutathione-sepharose beads. Activated Rac1 was then detected by anti-HA immunoblotting. As shown in Figure 7A, 3BP2 activated Rac1 (6-fold increase compared to basal activity). Under the same conditions, overexpression of Vav1 led to a 8-fold increase of Rac1 activity. We next examined whether 3BP2 required the activity of Vav proteins and Rho GTPases to activate NFAT in B cells. Overexpression of GEF-inactive forms of Vav1 or Vav2 (L213A and L212A, respectively) (Figure 7B), and of dominant-negative mutant forms of RhoA, Rac1, and Cdc42 (RhoN19, RacN17, and Cdc42N17, respectively) (Figure 7C) blocked 3BP2-induced NFAT activation in Daudi B cells. These data suggest that 3BP2 acts upstream of Vav and Rho proteins in the signaling pathways required for gene activation by BCR.
Discussion

In this study, we analyzed the role of the cytoplasmic adaptor 3BP2 (also known as SH3BP2) in BCR signaling. We provide biochemical and functional evidence that 3BP2 expression in B cells plays an important role in BCR-mediated activation of NFAT transcriptional activities through its interaction with members of the Vav family of Rho GTPases activators.

Immunoreceptors engagement on leukocytes activates non receptor tyrosine kinases of the Src, Syk and Tec families, which promote the assembly of signaling complexes composed of key enzymes connected by adaptor proteins. 3BP2 is an ubiquitous adaptor with preferential expression in hematopoietic cells, whose function remains ill-defined. However, both its original cloning as a binding protein of Abl SH3 domain, its subsequent isolation as a Syk-kinase interacting protein in lymphoid cells, and recent works in NK and mast cells, suggested an important role in hematopoietic cells. In further support to this idea, 3BP2 was shown here to play a direct and active role in BCR signaling. 3BP2, which is abundantly expressed in various B cell lines (Figure 1) and normal B lymphocytes (data not shown), is rapidly and transiently tyrosine phosphorylated after BCR aggregation. The kinase responsible for this phosphorylation was not identified, but we show that 3BP2 is tyrosine phosphorylated following expression of Fyn and Syk, but not Btk, in COS cells. 3BP2 contains several tyrosine phosphorylation sites, one of which (Y183LEP) being predicted to be a Vav1 and PLCγ binding motif, two proteins found to interact with 3BP2 in stimulated B cells. The function of 3BP2 in FcR signaling in NK and mast cells apparently involves its tyrosine phosphorylation by kinases of the Src and Syk families, and 3BP2 binds the Src PTKs Fyn and Lyn. Together these observations suggest that 3BP2 is a critical partner and substrate of Src and Syk PTKs in the signaling pathways of multiple Immunoreceptors, including BCR.

To gain understanding of 3BP2’s role in BCR signaling, we screened a yeast two-hybrid B cell library for 3BP2 interacting proteins. 3BP2 was found to constitutively interact with Vav1 and Vav2, two guanine nucleotide exchange factors for Rho family GTPases which...
play a critical role in T and B lymphocytes development and growth. The third member of the Vav family, Vav3 was not found during our screen. However, we found that it coimmunoprecipitates with 3BP2, suggesting that 3BP2 is a common partner of Vav proteins in hematopoietic cell signaling. The mapping of the 3BP2-Vav1/2 interaction indicates that it involves a proline-rich domain of 3BP2 (aa 201 to 240 or PR1) corresponding to the previously identified Abl SH3 binding site. Studies have shown that Vav also associates Bcr-Abl in leukemic cells. An interesting issue would be therefore to examine whether the occupation of PR1 domain by Vav proteins could prevent the simultaneous binding of Abl SH3 domain to 3BP2 and how this could affect cell signaling.

The interaction between 3BP2 and Vav proteins appears far more complex since 3BP2 SH2 domain binds tyrosine phosphorylated Vav proteins from BCR-stimulated B lymphocytes. Importantly, 3BP2 and Vav1 also co-precipitate in alkyl-glycosidic detergent conditions under which membrane lipid rafts are dissociated, showing that this interaction is not due to indirect associations with rafts. A predicted binding sequence for 3BP2 SH2 domain was determined as to be YEN, a motif found in LAT but not within Vav1 and Vav2 sequence. Further studies are thus required to determine the location of the 3BP2 SH2 binding site on Vav proteins. Recently, Jevremovic et al. described that Vav1 and PLC-γ SH2 domains associate 3BP2 upon phosphorylation of its tyrosine residue in activated NK cells. Tyr183 lies within the tyrosine phosphorylation site Y183LEP, which constitutes a Vav1 and PLC-γ binding motif according to previous studies. We also detected a Vav2 SH2-dependent interaction with tyrosine phosphorylated 3BP2 in B cells, in addition to the constitutive, SH3-dependent interaction. Interestingly, mutation of 3BP2 Tyr 183 indicates that this residue is required for optimal adaptor function of 3BP2 in B cells (I.F. and M.D., unpublished data) and for FcR-mediated NK cell cytotoxicity. Thus, there are apparently three different mechanisms of interaction between 3BP2 and Vav proteins: first, a basal interaction mediated by a proline-rich domain of 3BP2 and the SH3 domain(s) of Vav proteins; second, an activation-induced interaction between the SH2 domain of 3BP2 and phosphorylated Vav1/2; third an interaction between tyrosine phosphorylated 3BP2 and the SH2 domain of Vav1. This multiplicity of interactions could explain why the deletion of the...
proline-rich domain PR1 only partially reduced 3BP2-induced NFAT activation in B cells (Figure 5) and has almost no effect in T cells. Alternatively, this domain of 3BP2 could be implicated in distinct cellular functions through other molecular partners like c-Abl, Fyn or Lyn.

Finally, what could be the function of the 3BP2/Vav complex in B cells? Several observations point to a role in a PLC-γ-dependent pathway involved in NFAT activation. First, Vav proteins play pivotal roles in PLC-γ, calcium and NFAT regulation, and the major defect of vav1/-/- cells is a reduced PLC-γ activation and calcium movements following Immunoreceptors stimulation. Similar to Vav1/2 proteins, 3BP2 overexpression induced NFAT activation in B cells. Consistent with the reduced NFAT activities seen in 3BP2 knock down T and B cells (Figure 6), expression of 3BP2 SH2 domain decreased NFAT activation both in T and B cells (Figure 5). 3BP2 interacts with several proteins involved in PLC-γ pathways, including Syk and PLC-γ, itself. In T, NK, and basophilic cells, 3BP2 SH2 domain also associated phosphorylated LAT, a 36/38-kDa raft-enriched adapter protein required for PLC-γ signaling. Thus, the function of 3BP2 in BCR signaling shares similarities with those required for PLC-γ activation in other Immunoreceptors-stimulated hematopoietic cells. Interestingly, pull-down assays show that 3BP2 interacted with an unidentified 30-35 kDa phosphorylated protein in activated B cells. Whether this protein could be LAB/NTAL, the counterpart of LAT in B cells remains to be determined. Vav proteins also bind BLNK/SLP-65, a central adaptor of B cell signaling. Importantly, we did not observe the presence of BLNK in the 3BP2/Vav complex (data not shown), suggesting that 3BP2 coordinates the assembly of distinct molecular complexes involved in B cell signaling. Finally, 3BP2-dependent NFAT activation in B cells is blocked by GEF inactive forms of Vav1 and Vav2, and by dominant negative mutants of Rho GTPases, including Rac1. Rac1 has been involved in the regulation of NFAT activities in lymphocytes, and we show here that 3BP2 can increase Rac1 activity in T cells (Figure 7). Because Rho GTPases regulate a broad range of cellular functions, one could speculate that an important function of 3BP2 in hematopoietic cells is to promote the assembly of signaling complexes implicated in gene regulation through Vav proteins and Rho GTPases.
Acknowledgments

We thank T. Trenkle and M. McClelland for the Vav3 cDNA; E. Lemichez and P. Boquet for HA-tagged Rac1 expression plasmids; M. Ticchioni and S. Tartare-Deckert for discussion.

IMMUNOBIOLOGY

FIGURES LEGENDS

Figure 1: 3BP2 is phosphorylated by BCR engagement. A. Lysates of various B cell lines were analyzed by western-blot for 3BP2 expression. ERK2 expression was use as control to quantify protein levels in each lane. B. Daudi cells were transfected with a plasmid encoding HA-tagged 3BP2 or empty vector. HA-immunoprecipitates were then probed with anti-3BP2 or anti-HA antibodies. The membrane was reprobed with anti-HA antibody to control 3BP2 protein expression. C. BCR cross-linking results in 3BP2 tyrosine phosphorylation. Daudi cells were stimulated for 5 min with anti-IgM antibody (2 μg/ml). Immunoprecipitates were prepared with anti-3BP2 antibody and probed with antibodies to phosphotyrosine and 3BP2. D. COS-1 cells were transiently cotransfected with expression plasmids encoding HA-tagged 3BP2 and Fyn, Syk or Btk constructs. HA-immunoprecipitates were probed with anti-phosphotyrosine antibody. The membrane was reprobed with anti-HA antibody to control 3BP2 protein expression.

Figure 2: Interaction of 3BP2 with Vav family members. A. A yeast two-hybrid screen of a human lymphocyte library using LexA-3BP2 as bait was performed. Shown are the accession number of the different Vav cDNAs isolated during this screen, and the number of independent clones for each cDNA. B. COS-1 cells were transiently transfected with expression plasmids encoding HA-tagged 3BP2, myc-tagged Vav1, myc-tagged Vav2 or combinations of these plasmids as indicated. Immunoprecipitates were prepared with anti-HA antibody and probed with anti-myc antibody. The membranes were then reprobed with anti-HA antibody to control 3BP2 protein expression. C. A combination of HA-tagged 3BP2 and
myc-tagged Vav3 were expressed in COS-1 cells and co-immunoprecipitations were performed as described above.

**Figure 3: Binding of 3BP2 to Vav1 in B cells.** A. Interaction between endogenous 3BP2 and Vav1 in B cells. Daudi cells were activated for 0 or 5 min with anti-IgM antibody and lysed in NP-40 lysis buffer supplemented with 0.1% SDS. Immunoprecipitates were prepared with anti-3BP2 or irrelevant (control) antibodies and probed with anti-phosphotyrosine antibody. The membrane were then stripped and reprobed with antibodies against 3BP2 and Vav1. B. Interaction between 3BP2 and Vav1 in lipid rafts-dissociating conditions. Unstimulated Daudi cells were lysed in 1% Octylglucoside lysis buffer, and immunoprecipitates were prepared with anti-Vav1 or irrelevant (control) antibodies and probed with anti-3BP2 antibody. The membrane were then stripped and reprobed with antibodies Vav1. C and D. In vitro interaction between 3BP2 and Vav proteins. Lysates from unstimulated (-) or anti-IgM stimulated (+) Daudi cells were mixed with GST or GST Vav2 SH3-SH2-SH3 fusion proteins (B), or with GST or GST 3BP2 SH2 fusion proteins (C) that were immobilized on glutathione beads. Bound proteins were detected by immunoblotting with the indicated antibodies.

**Figure 4: Mapping of the constitutive binding domain of Vav1/2 on 3BP2.** A. Schematic structures of 3BP2 mutants used in these experiments. The PH, proline-rich (PR), and SH2 domains are represented by black, white, and grey boxes, respectively. COS-1 cells were transiently cotransfected with expression plasmids encoding myc-tagged Vav1 (B) or Vav2 (C), and various HA-tagged 3BP2 mutant constructs. Immunoprecipitates were prepared with anti-HA antibody and probed with anti-myc antibody. The membranes were then stripped and reprobed with anti-HA antibody to control 3BP2 protein expression.

**Figure 5: Involvement of 3BP2 in BCR-mediated activation of NFAT.** A. Daudi cells were transiently transfected with various 3BP2 mutant constructs, NFAT reporter plasmid, and Renilla luciferase plasmid (pRL-TK) used as internal control reporter. 24 h after transfection, cells were either left unstimulated, or stimulated with anti-IgM (2 μg/ml) for 6 hours, and
harvested for the dual-luciferase assay. The luciferase activity was normalized by the Renilla luciferase activity and expressed as fold increase relative to the basal activity seen in unstimulated mock-transfected cells. Values represent the mean +/- SD from triplicate samples. The lower panel shows the relative expression of each 3BP2 constructs. B. Daudi cells were transfected with an expression plasmid encoding HA-tagged 3BP2 SH2 (aa 454-559), NFAT reporter plasmid, and Renilla luciferase plasmid used as internal control reporter. Cell stimulation and luciferase assay were performed as above.

**Figure 6: RNA interference of 3BP2 decreases BCR signaling to NFAT.** Jurkat (A) or Raji (B) cells were transfected with 3BP2 siRNA (si3BP2) or control siRNA (siGFP) in the presence of fluorescein-conjugated control siRNA. After 24h, cells were sorted by FACS, lysed and protein expression was determined by immunoblotting with antibodies against 3BP2 and ERK2 (right panels). For determination of NFAT activity in 3BP2 knock down cells, Jurkat (A) or Raji (B) cells were electroporated with 2 μg siRNA, 15 μg NFAT reporter and 3μg of Renilla luciferase plasmid. After 18h, cells were stimulated or not for 6h and luciferase activity was measured and normalized as described above (left panels). Values represent the mean +/- SD from triplicate samples.

**Figure 7: Functional cooperation between 3BP2, Vav proteins, and Rho GTPases during NFAT activation.** A. 3BP2 activates Rac1 in Jurkat T cells. Cells were transfected with the indicated plasmids. After 24h, active forms of HA-Rac1 were captured by incubation of lysates with a GST-PDB fusion protein and glutathione beads. After extensive washings, bound HA-Rac1 proteins were detected by anti-HA immunoblotting. Expression of total HA-Rac1 was assessed on aliquots of cell lysates. Fold stimulation of GTP-bound HA-Rac1 was determined following normalization against total HA-Rac1 (left panel). The average of two representative experiments is shown (right panel). Daudi cells were cotransfected with 5 μg of NFAT luciferase reporter and HA-tagged 3BP2 in the presence of either (B) 30 μg of Vav1 L213A (Vav1 DN) or Vav2 L212A (Vav2 DN) or (C) 30 μg of Rho N19, Rac N17 or Cdc42 N17. Luciferase activity was measured as described above. Values represent the mean +/- SD.
