Mechanism of Action of SNS-032, a Novel Cyclin Dependent Kinase Inhibitor, in Chronic Lymphocytic Leukemia

Short title: Transcriptional Inhibition by SNS-032 in CLL

Abstract

Inhibitors of cyclin dependent kinases (Cdks) have been reported to have activities in CLL cells by inhibiting Cdk7 and Cdk9 that control transcription. Here we studied the novel Cdk inhibitor SNS-032, which exhibits potent and selective inhibitory activity against Cdk2, Cdk7 and Cdk9. We hypothesized that transient inhibition of transcription by SNS-032 would decrease anti-apoptotic proteins, resulting in cell death. SNS-032 effectively killed CLL cells in vitro regardless of prognostic indicators and treatment history. This was associated with inhibition of phosphorylation of RNA polymerase II and inhibition of RNA synthesis. Consistent with the intrinsic turnover rates of their transcripts and proteins, anti-apoptotic proteins such as Mcl-1 and XIAP were rapidly reduced upon exposure to SNS-032, whereas Bcl-2 protein was not affected. The initial decrease of Mcl-1 protein was due to transcriptional inhibition rather than cleavage by caspase. Compared to flavopiridol and roscovitine, SNS-032 was more potent, both in inhibition of RNA synthesis and at induction of apoptosis. SNS-032 activity was readily reversible; removal of SNS-032 reactivated RNA polymerase II, which led to re-synthesis of Mcl-1 and cell survival. Thus, these data support the clinical development of SNS-032 in diseases that require short lived oncoproteins for survival.

Key words: SNS-032, CLL, transcription, RNA polymerase II, Mcl-1
Introduction

CLL is characterized by the gradual accumulation of small, mature lymphocytes, with typical B-cell markers. Several lines of evidence suggest that the survival advantage of CLL lymphocytes is due to the over-expression of anti-apoptotic proteins of the Bcl-2 family. The Bcl-2 family consists of both anti-apoptotic and pro-apoptotic proteins that share sequence homology within conserved Bcl-2 homology (BH) domains. Bcl-2 and Mcl-1 are anti-apoptotic proteins that lend a survival advantage to CLL. They act by binding to pro-apoptotic proteins to prevent them from disrupting the mitochondrial outer membrane, an action that initiates apoptosis. On the other hand, XIAP inhibits the activity of caspases 3, 7 and 9, preventing them from the induction of cell death. The mitochondria of the CLL cells are “primed” with death signals and the cells require the continuous expression of anti-apoptotic protein to maintain their survival.

In such a biological context, agents that aim at antagonizing or diminishing the anti-apoptotic proteins cause the release of pro-death signals to commit cells to apoptosis. This has been a focus of new therapeutics in CLL. One of such approaches uses small molecular BH3 mimetics designed to interfere with interactions of anti- and pro-apoptotic proteins at the BH3 domain. These compounds, including ABT-737, GX15-070, Gossypol/AT-101 and TW-37, have shown impressive activity in vitro and are currently under investigation in clinical trials. A second approach is aimed at decreasing the expression level of Bcl-2. For example, Oblimersen (Genasense, Genta Inc.) is an antisense oligonucleotide designed to target human Bcl-2 mRNA and reduce Bcl-2 expression. In addition, clinical trials are ongoing with AS1411 (Antisoma Research Ltd), a nucleic acid aptamer that competes with Bcl-2 mRNA for binding to nucleolin; an action that destabilizes Bcl-2 mRNA and reduces its protein expression.
A third approach uses transient exposure to inhibitors of cyclin dependent kinases (Cdk) required for transcription, thereby selectively affecting short lived anti-apoptotic proteins\textsuperscript{15-17}. Although Cdk family members commonly regulate cell cycle events, some members are associated with transcription control. In particular, Cdk7 and Cdk9, have major roles in the initiation and elongation steps in transcription. For instance, Cdk7 is an integral component of the transcription factor TFIIH,\textsuperscript{18} which phosphorylates the Ser-5 in the heptad repeats of the C-terminal domain (CTD) of RNA polymerase II (Pol II), to facilitate transcription initiation. Cdk9, a portion of the elongation factor P-TEFb,\textsuperscript{19,20} performs a complementary function by phosphorylating Ser-2 in the CTD of RNA Pol II, which is required for transcript elongation. While the prolonged inhibition of Cdk9 and Cdk7 will eventually affect all transcripts produced by RNA Pol II and subsequently their proteins, the immediate effect will be on those transcripts and proteins with inherently rapid turnover rates,\textsuperscript{21} such as Mcl-1 and XIAP. In such a context, inhibiting transcription would decrease Mcl-1 and XIAP expression, thus releasing their ability to block primed cells from initiating apoptosis.

This provided a rationale for using Cdk7 and Cdk9 inhibitors in CLL as well as other diseases that depend on such intrinsically labile proteins for survival. As such, both flavopiridol and roscovitine have shown in vitro activity in inhibiting RNA Pol II and reduced expression of Mcl-1 and XIAP, and efficiently induced apoptosis in CLL and multiple myeloma cells in vitro.\textsuperscript{15,16} As the majority of the CLL cells are not cycling, the inhibition on the cell cycle regulating Cdks may not play a major role in their mechanism of action in CLL. Although disappointing in its initial clinical trials, flavopiridol administered on a pharmacokinetically-derived dose schedule aimed at sustaining LC\textsubscript{50} plasma levels for 4 hr has shown a 45\% partial
response rate in phase 1 trials in relapsed, high risk CLL\textsuperscript{22} and a 48\% response in a recently reported phase 2 trial.\textsuperscript{23}.

Here we present investigations of SNS-032, a novel and selective Cdk inhibitor that has emerged in clinical trials. SNS-032 (formerly known as BMS-387032), was originally synthesized by Bristol-Myers Squibb Pharmaceutical Research Institute in an effort to generate a selective inhibitor of Cdk2. This compound was chosen for clinical development based on its strong and selective inhibitory activity for Cdk2 (IC\textsubscript{50} 38 nM) over Cdk1 and Cdk4 (IC\textsubscript{50}s 480 and 925 nM, respectively) and a panel of unrelated kinases, its moderately low protein binding (63\%) and its efficacious antitumor activity.\textsuperscript{24} Three phase 1 studies toward metastatic refractory solid tumors or lymphoma showed that this drug was well tolerated at three different dose schedules.\textsuperscript{25-27} Only after the compound was licensed by Sunesis Pharmaceuticals was it realized that SNS-032 was also potent against Cdk 9 (IC\textsubscript{50} 4 nM) and Cdk7 (IC\textsubscript{50} 62 nM), the Cdks that involves in the regulation of transcription.\textsuperscript{28} A phase 1 dose-escalation trial of SNS-032 was conducted by Sunesis Pharmaceutical Inc. given weekly as a 1-h intravenous infusion to patients with advanced solid tumors.\textsuperscript{29} The drug was well tolerated in a total of 21 patients enrolled in this study, three (15\%) of them had stable disease. Another phase 1 multi-center trial of SNS-032 is currently ongoing in patients with advanced B-lymphoid malignancies, including CLL and multiple myeloma, using a pharmacokinetically-derived dose schedule that targets the LC\textsubscript{90} (115 ng/ml, 300 nM)\textsuperscript{30} for 6 hr.\textsuperscript{31} The current investigation tested the hypothesis that transiently inhibiting the synthesis of transcripts of anti-apoptotic proteins that are necessary for CLL survival will result in the decrease in these proteins and cause the relatively rapid onset of cell death. Our results emphasized the importance of continued suppression of Mcl-1 expression to the initiation of apoptosis in CLL cells.
Patients, materials, and methods

Patients

Samples from 51 CLL patients were used in this study. Median age of the patients was 63 (range, 42 to 83) with 31 male patients and 20 female patients. Their median white blood cell count was 43,000/µl (range, 9,500 to 235,000/µl). The median lymphocyte percentage was 89% (range, 63% to 99%). Detailed patient characteristics are summarized in Table 1. Approval was obtained from the University of Texas M. D. Anderson Cancer Center Institutional Review Board for this investigation, and all patients agreed to participate and provided informed consent for use of their cells for in vitro studies, in accordance with the Declaration of Helsinki.

Isolation of CLL lymphocytes

Peripheral blood samples from the CLL patients were collected in heparin vacutainer tubes and centrifuged at 1500 rpm for 15 min to separate the plasma. The plasma (upper layer) was removed and saved for cell culture. The lower layer was diluted with phosphate-buffered saline (PBS), and the mononuclear cells were isolated by Ficoll density-gradient centrifugation. The isolated CLL cells were cultured at 1 × 10^7 cells/ml in RPMI 1640 medium (Sigma-Aldrich, St. Louis, MO) containing 10% of autologous plasma.

Materials

SNS-032 was provided by Sunesis Pharmaceuticals Inc. (South San Francisco, CA). It was dissolved in dimethylsulfoxide (DMSO) at 10 mM, and stored at –20°C in small aliquots. [3H]uridine (50 Ci/mmol) was purchased from Moravek Biochemical Inc (Brea, CA). Flavopiridol was obtained from the Drug Synthesis and Chemistry Branch, Division of Cancer
Treatment, National Cancer Institute (Bethesda, MD). It was dissolved in DMSO at 10 mM, and stored at -70°C in small aliquots. Roscovitine was purchased from LKT laboratories, Inc (St. Paul, MN). It was dissolved in DMSO at 10 mM and stored at -20°C in small aliquots. Annexin V-FITC Apoptosis Detection Kit was purchased from BD Biosciences (Franklin Lakes, NJ). Propidium Iodide (PI) solution (1 mg/ml), and tetramethyl rhodamine methyl ester (TMRM) were purchased from Sigma Aldrich Inc. ZVAD-FMK (methyl ester) was purchased from MP Biomedicals (Solon, OH). MG-132 was from EMD Biosciences (Gibbstown, NJ).

Quantitation of cell death

Cell death in normal lymphocytes or CLL cells was evaluated by flow cytometry analysis using annexin V and PI double staining. After the drug treatment, CLL cells (1x10^6 cells) were washed with PBS and resuspended in 200 μl binding buffer with 5 μl annexin-FITC, and incubated for 15 min in the dark at room temperature. After staining, 300 μl binding buffer with 5 μl of 50 μg/ml PI were added to each tube. Samples were analyzed immediately with a Becton Dickinson FACS Calibur flow cytometer (Becton Dickinson, Franklin Lakes, NJ). Data acquisition and analysis were performed by the CellQuest program (Becton Dickinson). Cells stained positive for either annexin V or PI were considered dead cells.

Mitochondrial membrane potential

Change in mitochondrial membrane potential was measured by flow cytometry using the fluorescent cation TMRM and annexin V double staining. After the drug treatment, CLL cells (1x10^6 cells) were washed with PBS and resuspended in 200 μl binding buffer with 5 μl annexin-FITC and 200 nM TMRM, and incubated for 15 min in dark at room temperature. After staining,
300 μl binding buffer were added to each tube. Samples were analyzed immediately with Becton Dickinson FACS Calibur flow cytometer.

**Measuring the RNA synthesis**

RNA synthesis was measured by quantitating incorporation of \(^{3}\)Huridine into the perchloric acid-insoluble materials. Briefly, after incubation with the drugs, CLL cells were labeled for 1 hr with \(^{3}\)Huridine (10 μCi/ml). The cells were then washed twice with 10 ml of ice-cold PBS and then lysed while vortexing with 0.5 ml H\(_2\)O and 0.5 ml 0.8 N perchloric acid. Following centrifugation, the pellet was washed once with 1 ml 0.4 N perchloric acid, dissolved in 1 ml H\(_2\)O with 50 μl of 10 N KOH overnight. The supernatant was then transferred to scintillation vials to quantitate radioactivity.

**Immunoblotting**

CLL cells were lysed as described previously\(^{15}\). Cell lysate proteins (20 μg) were separated by SDS-polyacrylamide gel electrophoresis and then electro-transferred to a nitrocellulose membrane (GE Osmonics Labstore, Minnetonka, MN). The membranes were blocked for 1 hr in PBS containing 5% nonfat dried milk and then incubated with primary antibodies for 3 hr, followed by incubation with secondary antibodies conjugated with fluorescent dyes for 1 hr. The blots were scanned by an Odyssey Infrared Imaging system (LI-COR Biosciences, Lincoln, Nebraska) to obtain images and quantitations. The antibodies to Mcl-1 (S-19), Bcl-2 (100), Cdk7 (C-4) and Cdk9 (C-20) were purchased from Santa Cruz Biotechnology (Santa Cruz, CA). The antibody to PARP was from Biomol International Inc. (Plymouth Meeting, PA). XIAP antibody was from BD Biosciences Pharmingen (San Diego, CA). Antibodies for total RNA Pol
II (8WG16), phosphorylated CTD at Ser2 (H5) or Ser5 (H14) were purchased from Covance Research Products, Inc (Berkeley, CA). Alexa Fluor® 680 goat anti-mouse IgG was purchased from Invitrogen (Carlsbad, California). IRDye 800CW Goat Anti-rabbit IgG was from LI-COR Biosciences (Lincoln, Nebraska)

RNA isolation and Real-time quantitative PCR

Total cellular RNA was isolated from the primary CLL cells using the RNeasy mini kit (Qiagen, Valencia, CA) with DNase digestion to completely remove the genomic DNA. Total RNA (20-50 ng) was used for the one-step real-time PCR reaction in the TaqMan® One-Step RT-PCR Master Mix (Applied Biosystems, Foster City, CA). Each PCR reaction was carried out in a 25 µl volume on 96-well optical reaction plate for 30 min at 48°C for reverse transcription reaction, followed by 10 min at 95°C for initial denaturing, then followed by 40 cycles of 95°C for 15 seconds and 60°C for 2 min in the 7900HT Sequence Detection System (Applied Biosystems, Foster City, CA). The relative gene expression was analyzed by the Comparative Ct method using 18s ribosomal RNA as endogenous control, after confirming that the efficiencies of the target and the endogenous control amplifications were approximately equal. All the primers and probes and RT-PCR reaction buffers were purchased from Applied Biosystems.

Statistical analysis

Statistical analysis was carried out by the student’s t test using the GraphPad Prism software (GraphPad Software, Inc., San Diego, CA). A p-value less than 0.05 was considered to be statistically significant.
Results:

SNS-032 induced apoptosis in CLL cells regardless of the prognostic factors and treatment history

The cytotoxicity of SNS-032 was evaluated using annexin V/PI staining followed by flow cytometry after both a short (6 hr) and a longer incubation period (24 hr). The 6-hr time point was chosen because the SNS-032 is administered as a 15 min loading dose followed by a 6-hr continuous infusion in the current clinical trial.\[^{31}\] CLL cells from 6 patient samples incubated with a range of SNS-032 concentrations (0.1 \(\mu\)M to 1 \(\mu\)M) for 6 hr induced cell death by 16 to 18\% relative to untreated CLL cells (15.1 \(\pm\) 3.7 \(\%\), mean \(\pm\) SD) (Figure 1A). In contrast, after 24-hr, cell death increased significantly in a concentration-dependent manner, which reached a maximum at 0.3 \(\mu\)M (82.2 \(\pm\) 8.2 \(\%\), mean \(\pm\) SD), whereas the viabilities of the time-matched control cells were well maintained (15.1 \(\pm\) 4.3 \(\%\) cell death, data not shown). A recent report of the phase 1 clinical trial of SNS-032 in B cells malignancies showed that plasma SNS-032 above 0.3 \(\mu\)M was well maintained during the infusion in patients who received total doses of 75 mg/m\(^2\).\[^{31}\] The induction of apoptosis was selective for CLL cells, as 0.3 \(\mu\)M SNS-032 only induced 14.5\% \(\pm\) 2.9 (mean \(\pm\) SD) cell death in mononuclear cells isolated from healthy donors, compared to a 73.8\% \(\pm\) 12.8 cell death inductions in a set of 8 CLL samples (Figure 1B). Little variation was observed within the 6 samples used in Figure 1A, although the prognostic indicators of each patient varied. As shown in Table 1 (patients 1 to 4, 10 and 12), two of the six patients had received prior treatment, three had chromosomal abnormalities, three had unmutated immunoglobulin heavy-chain variable-region genes (IgV\(H\)),\[^{32}\] and 2 expressed high 70-kD zeta-associated protein (ZAP-70),\[^{33}\] indicating aggressive disease. Thus, these data suggested that SNS-032 may be toxic to CLL cells regardless of patient characteristics. To extend this
observation, we compared 0.3 μM SNS-032 induced cell death after 24-hr incubation in 43 CLL samples. The net induced apoptosis averaged 61.6 ± 12.1 % (mean ± SD) after subtracting the cell death in time-matched controls (15.6 ± 8.9) (Figure 1C). There was no significant difference between cells from patients with either favorable or poor prognosis features, including Rai stage, beta-2-microglobulin (B2M) levels, IgV_H mutation status, ZAP-70 expression, previous treatment history, and chromosomal abnormalities. There was no evidence of a loss of potency in samples derived from fludarabine resistant patients. In a group of samples analyzed by fluorescence in situ hybridization that had deletion of 17p, indicative of TP53 gene deletion (range from 8.5-94.5%), there was no significant difference in cell death compared to the rest of the group that had normal TP53 gene loci. Similar results were observed for patients with del 11q, diagnostic of ATM gene deletion (range from 8.5 to 94.5%). These results indicate that SNS-032 may induce apoptosis by a mechanism that is independent of p53 and ATM expression in the CLL cells.

**Inhibition of RNA synthesis by SNS-032 in CLL cells**

Treatment of CLL cells from the same group of 6 patient samples in Figure 1A with SNS-032 for 6 or 24 hr was associated with a decrease in phosphorylation of Ser2 and Ser5 of the CTD of RNA Pol II that appeared to be both concentration and time-dependent (Figure 2A). SNS-032 decreased the ratios of pSer2/total RNA Pol II and pSer5/total RNA Pol II in a concentration-dependent manner (Figure 2B) that was remarkably consistent among samples. There was greater inhibition on Ser2 phosphorylation than that of Ser5, consistent with a lower IC_{50} for the inhibition of Cdk9 compared to Cdk7 (4 nM versus 62 nM). This was associated with inhibition of RNA synthesis, measured by tritiated uridine incorporation in the same group.
of 6 patient samples, which decreased in a concentration-dependent manner after SNS-032 treatment (Figure 2C). There was no apparent time dependence, indicating that the phosphorylation of RNA Pol II was inhibited rapidly after addition of SNS-032. In fact, 0.3 μM SNS-032 reduced 88.3% of [3H]uridine incorporation after 1 hr (average of 2 patient samples each measured in triplicate, data not shown). The protein levels of Cdk7 and Cdk9 were stable after 6 hr of SNS-032 exposure, and declined at 24 hr (Figure 2A). The discordance between Cdk7 and Cdk9 protein levels and the Pol II phosphorylation status at 6 hr (Figure 2B) indicated that reducing of Cdk7 and Cdk9 levels could not account for the decreased RNA Pol II phosphorylation. Rather, the rapid inhibition on the activity of Cdk7 and Cdk9 led to the inactivation of RNA Pol II.

Both flavopiridol and roscovitine are inhibitory to Cdk9 and Cdk7, and affect Pol II phosphorylation status. In direct comparisons on CLL cells, SNS-032 was about 10 to 20 fold more potent than flavopiridol and about 400- to 700-fold more potent than roscovitine in the inhibition of RNA synthesis (Figure 3A) and induction of cell death (Figure 3B). Consistent with IC₅₀ values against Cdk9 and Cdk7, these data indicate that SNS-032 is a more potent agent in these studies.

**SNS-032 decreased the mRNA and protein levels of anti-apoptotic proteins**

The most sensitive targets of transcription inhibitors are likely to be transcripts and proteins that intrinsically turn over rapidly. SNS-032 induced a rapid concentration-dependent decrease in the mRNA levels of Mcl-1 (Figure 4A). After 6 hr with 0.3 μM SNS-032, Mcl-1 mRNA was reduced to 27% of controls and to 10% by 1 μM SNS-032 (Figure 4A). There was no apparent
difference between 6 and 24 hr, probably because of the intrinsically short half-life of Mcl-1 mRNA. In contrast, there was a time- and concentration-dependent decrease of XIAP and Bcl-2 mRNA. This was associated with decreases in the protein levels of Mcl-1 and XIAP (Figure 4B), although there was no apparent decrease in Bcl-2 protein levels. Similar analyses from all 6 patient samples were quantitated and were summarized in Figure 4C. The rate of decrease in the protein levels of Mcl-1 and XIAP were proportional to their intrinsic half-lives, with Mcl-1 being the most labile. There was no significant change in the Bcl-2 protein, consistent with a much longer protein half-life.37

When the supply of mRNA for translation is shut down by SNS-032, the decrease in total Mcl-1 protein reflects the degradation of existing Mcl-1 protein by proteases, such as through the proteosome degradation pathway.38 Alternatively, Mcl-1 protein can also be degraded by activated caspase-3,39 which may cleave Mcl-1 into small fragments. To determine the extent to which each of these mechanisms accounts for Mcl-1 protein turnover, CLL cells were pre-incubated with the caspase-3 inhibitor, ZVAD, for 1 hr before exposure to 0.3 μM SNS-032 for 8 hrs. ZVAD inhibited the activity of caspase-3, shown by the blocking of PARP cleavage (Figure 4D). However, ZVAD did not block the degradation of Mcl-1 protein, indicating that this was independent of the caspase activity. In contrast, the proteosome inhibitor, MG-132, stabilized Mcl-1 protein in the cells and partially restored the Mcl-1 protein level. That Mcl-1 protein was only partially restored by MG-132 is likely because caspase-3 is already activated in the cells, diminishing the protein. Therefore, this experiment indicated that the SNS-032-induced decrease of Mcl-1 was due to intrinsic turnover through the proteosome pathway following transcription
inhibition. The more limited proteolysis by caspase-3 probably occurred secondary to activation of the apoptotic process.

Upon removal of Mcl-1 protein, the freed pro-apoptotic binding partners are able to disrupt the mitochondrial membrane. Depolarization of mitochondrial membranes was quantitated by the loss of binding to the cationic dye TMRM. As shown in Figure 5, SNS-032 induced a time-dependent shifting of cells from the TMRM(+)/annexin(-) to the TMRM(-)/annexin(+) population, indicating loss of mitochondrial membrane potential was associated with the onset of cell death, likely initiated by the reduced Mcl-1 protein.

**Removal of SNS-032 reactivates transcription and restores Mcl-1 protein levels**

In order to relate the decrease in anti-apoptotic protein levels with the induction of cell death, it was important to determine the duration of exposure to SNS-032 that was optimal for CLL cell killing. Cells from four samples were incubated with 0.3 μM SNS-032 for as long as 24 hr; apoptosis was determined by annexin V /PI staining at 2-hr intervals. Cell killing by SNS-032 in vitro was evident at 6 hr, but was maximized between 10 and 12 hr (Figure 6A). In contrast, the viability of mock-treated control samples remained stable for 24 hr. To determine if additional cell killing occurred after removal of SNS-032, we measured cell death at 24 hr after a 6-hr incubation with SNS-032 followed by washing cells into drug-free medium. Cells incubated continuously with SNS-032 for 24 hr were used as the comparator for maximum cell kill. Following washing cells into fresh medium, there was no evidence of additional cell death beyond that observed after the 6-hr incubation (Figure 6B). Although there was a modest concentration-dependent cell killing after 6-hr incubation, death did not increase during the 18 hr after removal of SNS-032, even at the greatest concentration, 1 μM. Continuous incubation with
these SNS-032 concentrations for 24 hr generated a prominent concentration-dependent killing, as was also seen in Figure 1A. To investigate the reason for this lack of continued killing, CLL cells were incubated with 0.3 μM SNS-032 for 6 hr and one portion of the culture was washed into drug-free medium, whereas the other portion was maintained in the presence of drug. Immunoblotting analysis over time demonstrated that there was a rapid re-phosphorylation of Ser2 and Ser5 of the RNA Pol II CTD that was clearly evident 3 hr after washing cells out of the drug (Figure 6C). This was accompanied by the recovery of RNA synthesis (Figure 6D), again suggesting the linkage between these parameters. The kinetics of decrease in Mcl-1 and XIAP proteins was halted upon washing, and some recovery occurred (Figure 6C). Thus, upon SNS-032 removal, new proteins were synthesized to overcome their rapid degradation and restore the protein levels.

Discussion:

This study investigated the hypothesis that depriving cells of anti-apoptotic proteins by inhibition of transcription would initiate the irreversible process of apoptosis. CLL was used as a model because of the dependence of this disease on the continued expression of anti-apoptotic proteins for survival. Further, two such survival factors, Mcl-1 and XIAP, have intrinsically rapid turn-over rates in both transcripts and proteins. SNS-032, a potent inhibitor of both Cdk9 and Cdk7, blocked the transcription-enabling phosphorylations on RNA Pol II by these kinases. This was closely associated with decreases in Mcl-1 and XIAP transcripts, and subsequently of their proteins. Consistent with the working hypothesis, CLL cells initiated apoptosis within a few hours of Mcl-1 depletion. However, the action of SNS-032 was readily reversible, as its removal was followed by reactivation RNA Pol II, resumption of Mcl-1 expression and halting
further of cell death, emphasizing the importance of sustained suppression of these oncoproteins for cell killing.

Due to the heterogeneous clinical responses of CLL patients, cellular and molecular markers have been identified to predict the disease tendency or outcome of therapy. Rai\textsuperscript{40} and Binet\textsuperscript{41} staging systems have been widely used to assess disease status and treatment options, with Rai stages III and IV considered high risk and aggressive disease. Using interphase fluorescence in situ hybridization, cytogenetic lesions were identified in CLL patient cells, including the deletion of the short arm of chromosome 17 where the TP53 gene is located, or the long arm of chromosome 11 associated with the ATM gene. Evidence showed that these chromosome aberrations can be unfavorable prognosis to standard chemotherapy containing alkylating agents and purine nucleoside analogs.\textsuperscript{42} The absence of somatic mutation IgV\textsubscript{H} gene, or high expression of ZAP-70\textsuperscript{33} or CD38\textsuperscript{43} in the leukemia cells is also associated with aggressive disease. The combination of fludarabine, cyclophosphamide and rituximab is the most active regimen in the current treatment of CLL.\textsuperscript{35} Still, patients with high beta-2-microglobulin have significantly inferior responses than those who express lesser amounts of this protein. When responses to SNS-032 in vitro were compared in patient samples with either favorable or poor prognostic characteristics, there were no significant differences found among samples in each group (Figure 1C). These results indicate that SNS-032 induces apoptosis by a mechanism that is independent of these variables. The fact that CLL samples from 16 patients who failed other therapies were responsive to SNS-032 in vitro, suggests that SNS-032 may have the potential to overcome drug resistance in CLL therapy.

The activity of SNS-032 takes advantage of the dependence of CLL cells on anti-apoptotic proteins for survival. The phenomenon that some tumors are dependent upon the continuous
activity of specific oncogenes for sustaining their malignant phenotype was characterized as being “addicted” to the activity of the oncogene. This concept has provided a rationale for the development of targeted therapeutics specifically directed at inhibiting the activity of the particular oncogene product. In such an approach, the biologic context of the dependency of the tumor on oncogene function provides a basis for the therapeutic index. Recently, this rationale for cancer therapeutics has proved to be effective in the clinic. CLL cells are characterized by their addiction to the continuous presence of anti-apoptotic proteins to maintain their survival. Therapeutic strategies that remove these blocks will release the pro-apoptotic signal and initiate cell death. In addition, anti-apoptotic proteins such as Mcl-1 and XIAP, that sustain the CLL cell viability, are intrinsically short lived, thus their mRNA and protein levels will decrease rapidly by degradation when synthesis is stopped following inhibition of transcription. This biological context is likely critical for the clinical success of flavopiridol in CLL compared to its lack of activity in other diseases.

There is controversy of how important Mcl-1 is for CLL cell survival relative to Bcl-2. When measured quantitatively, CLL cells express a 4- to 14-fold less Mcl-1 compared to Bcl-2. In addition, in BH3 profiling assay, peptides derived from Noxa, which binds and inhibits Mcl-1, failed to cause cytochrome c release from mitochondria isolated from CLL cells. These data support the argument that that Bcl-2 may be the dominant anti-apoptotic protein sustaining the CLL cells. However, other evidence suggests that Mcl-1 plays an important role in CLL survival as well. Decreasing Mcl-1 alone is sufficient to induce a substantial amount of apoptosis in CLL cells in vitro: for example, when Mcl-1 expression was specifically knocked down by siRNA, there was a significant reduction in cell survival, and enhancement of chemosensitivity. In addition, our results with CLL cells treated with either SNS-032 or flavopiridol showed that
inhibition of transcription substantially reduced Mcl-1 and XIAP expression and induced cell death, while the Bcl-2 protein level remained stable, indicating that Mcl-1 may also be critical in sustaining the CLL cells. Thus, it is possible that it is the balance of the pools of the anti- and pro-apoptotic proteins, rather than expression of an individual protein, that controls the fate of the cells. For example, cellular resistance to Bcl-2 antagonists was associated with an over-expression of Mcl-1. Strategies that reduced Mcl-1 expression have shown synergy with the BH3 mimetic, ABT-737, which itself has little effect on Mcl-1 binding to pro-apoptotic proteins. Further, it was reported that the pro-apoptotic proteins released after reduction of Mcl-1 may again be sequestered by Bcl-2, thereby delaying the onset of apoptosis. These observations indicate that either diminishing Mcl-1 expression or antagonizing Bcl-2 binding will lower the buffering capacity of the pool of anti-apoptotic proteins. When this capacity is reduced below a critical point, the excess pro-apoptotic proteins will disrupt the mitochondrial membrane and induce cell death.

The observation that the inhibition of transcription by SNS-032 appeared to be reversible has important implications for therapeutic strategies. Upon washing out SNS-032 after 6 hr of incubation with CLL cells, RNA Pol II phosphorylation and uridine incorporation recovered within 3 hr, followed by repletion of short-lived proteins such as Mcl-1 and XIAP (Figure 6C). This indicated that synthesis of these proteins had resumed and viability of cells that had not initiated apoptosis was maintained. As maximal killing in vitro occurred after 10 to 12 hr of exposure to SNS-032, these results suggest that it may be necessary to expose the CLL cells to SNS-032 for such a duration in the clinic. In addition, these experiments indicate the importance of sustained suppression of Mcl-1 and XIAP in order to maximize induction of cell death, and emphasize the importance of these proteins for CLL survival. Finally, these experiments raise
the possibility that protein synthesis inhibitors that block the re-synthesis of Mcl-1, may extend the cytotoxicity of SNS-032. One of such inhibitors, homoharringtonine, has activity to reduce the Bcr-Abl oncoprotein in a chronic myelogenous leukemia (CML) cell line.\textsuperscript{50} It is currently being evaluated in a phase 2 clinical trial in Imatinib resistant CML patients with the T315I mutation. The combination effect of SNS-032 with homoharringtonine is under investigation.

SNS-032 was selected for development based on its favorable characteristics such as low protein binding, potency, and selective inhibition on a small subset of Cdks (Cdk2, 7 and 9). In comparison with other compounds with similar activities, flavopiridol is known for its high plasma protein binding, whereas only about 63\% of SNS-032 was bound in human serum.\textsuperscript{24} Its potency is evident in assays of both inhibition of RNA synthesis and induction of apoptosis when compared to flavopiridol and roscovitine. In addition, while both flavopiridol and SNS-032 have similar IC\textsubscript{50} values for Cdk9/cyclin T, SNS-032 is about 5 times more potent against Cdk7/cyclin H than is flavopiridol.\textsuperscript{36} In contrast, although roscovitine has inhibitory activity against each of these targets, concentrations required are 10 to 100 times greater. Further, flavopiridol and roscovitine inhibit Cdk1/cyclin B, Cdk4/cyclin D and Cdk6/cyclin D and Cdk5/p35 in similar concentration ranges as against Cdk7 and Cdk9, whereas SNS-032 is considerably less effective against these proliferation-related Cdks.\textsuperscript{28} Moreover, SNS-032 had little activity (IC\textsubscript{50} > 1000 nM) against 190 other kinases.\textsuperscript{28} Therefore, SNS-032 has biochemical and pharmacologic properties that differ from flavopiridol and roscovitine, which likely predict differing activities in the clinic.

In conclusion, this study demonstrated in vitro the action of a novel Cdk inhibitor, SNS-032, in CLL cells. In a recent report of an ongoing trial, SNS-032 concentrations above in vitro IC\textsubscript{90} (115 ng/ml or 0.3 \textmu M)\textsuperscript{30} were maintained for over 6 hr in patients who received total doses of 75
mg/m². Target modulation such as reduced Pol II phosphorylation, decrease of Mcl-1 and XIAP levels were demonstrated in CLL cells isolated from patients in this cohort. Apoptosis was detected by PARP cleavage at the completion of infusion. Thus, pharmacodynamic actions observed in vivo are consistent with the predictions of the present investigations in CLL cells in vitro. Additional investigations are required to provide rigorous proof-of-principle evidence for the actions of SNS-032 in the clinical setting.

**Acknowledgments**

This study was supported in part by research funding from Sunesis Pharmaceuticals to WP, The CLL Global Research Foundation, and by grants CA81534, CA100632 and Cancer Center Support Grant CA16672 from the National Cancer Institute, Department of Health and Human Services.

The authors are thankful to Susan C. Smith and Susan Lerner, Department of Leukemia, The University of Texas M. D. Anderson Cancer Center, Houston, Texas, for providing the patient information.

**Author Contributions:** R.C. conceptualized the project, designed and performed research, analyzed the data and wrote the paper. W.G.W. and M.J.K. identified CLL patients for inclusion in the study. S.C. performed research and analyzed the data. R.E.H. contributed to experimental design and analysis. J.A.F. contributed to experimental design and analysis, provided SNS-032. V.G., contributed to experimental design and analysis. W.P., conceptualized the project, directed experiment design and data analysis, wrote the paper.
Conflict of Interest Disclosure: R.E.H. and J.A.F. are employees of Sunesis Pharmaceuticals. W.P. and W.G.W. received research funding from Sunesis Pharmaceuticals.

</table>
Rai stage and B2M levels were assessed at the day of sample acquisition.

NA: information not available

*: B2M: Beta-2-microglobulin, mg/L

†: IgV_H gene with less than 98% homology with the corresponding germ-line gene was considered mutated.

‡: ZAP-70 expression was detected with either fluorescence in situ hybridization or flow cytometry. Sample with greater than 20% of CLL cells expressing ZAP-70 is considered ZAP-70 positive.

§: blank: patient did not receive fludarabine treatment

||: TP53 or ATM gene were detected using fluorescence in situ hybridization of bone marrow cells using fluorescent probes designed to detect the 17p13.1 (TP53 gene) region of chromosome 17 or the 11q22.3 (ATM gene) region of chromosome 11. Two hundred cells were analyzed for each probe. Numbers represent percentage of cells that are abnormal in at least one of the allele of the gene loci. A percentage >5% was reported.
Figure legends:

**Figure 1. SNS-032 potently induces apoptosis in CLL cells.** (A) Induction of apoptosis in CLL cells isolated from 6 patients at 6 (■) and 24 hr (●) exposure to SNS-032. Cell death was measured by annexin V/PI double staining and quantitated by flow cytometry analysis (mean ± SD). (B) SNS-032 is selective against CLL cells. Cell death induced by SNS-032 was compared between the averages of 8 CLL cells (●) to mononuclear cells isolated from 3 healthy donors (■). (C) SNS-032 induced similar cell death regardless of patient characteristics and treatment history. Cell death induced by 0.3 μM SNS-032 after 24-hr incubation was compared in CLL cells from patients with favorable or poor prognostic factors. A p value of less than 0.05 was considered significant. Induced cell death was calculated as the difference between cell death in drug treated samples minus that of time-matched controls. DMSO alone at highest concentration used here (0.01%) did not show toxicity to the CLL cells. *: sample number was too small to give a reliable p value.

**Figure 2. SNS-032 inhibited RNA synthesis in the CLL cells.** CLL cells were incubated with 0.1, 0.3 and 1 μM SNS-032 for 6 and 24 hr, the phosphorylation of RNA Pol II and Cdk7, Cdk9 expression levels were analyzed by immunoblotting, using antibodies towards the phosphorylated Ser2 or Ser5 sites of the CTD, as well as total RNA Pol II, total Cdk7 and Cdk9. (A) A representative immunoblot from patient 4. (B) Inhibition of phosphorylation of RNA Pol II at Ser2 (■) and Ser5 (●) sites and protein levels of Cdk7 (▲) and Cdk9 (▼) after 6 hr (left) and 24 hr (right) incubation with SNS-032 from the six patient samples in Figure 1A. Levels of phosphorylation were quantified from the blots, normalized to total Pol II, and then expressed as a percentage of time-matched controls (mean ± SD). Levels of Cdk7 and Cdk9 were normalized.
to Actin and expressed as percentage of time-matched controls (mean ± SD). (C) Inhibition of \(^{3}\text{H}\)uridine incorporation by SNS-032 in CLL cells. The inhibition of \(^{3}\text{H}\)uridine incorporation was measured in the same set of CLL samples at 6 (■) and 24 hr (●) in SNS-032. Data was presented as percentage of time-matched controls (mean ± SD; n=6 samples each performed in triplicate). The average dpm value for untreated samples was 109,740 ± 59,359 (mean ± SD).

**Figure 3. Comparison of the activity of SNS-032, flavopiridol and roscovitine in CLL cells.**
The inhibition of uridine incorporation after 6 hr (A) and inhibition of cell survival measured by annexin V/PI staining after 24 hr (B) were compared among SNS-032 (●), flavopiridol (■) and roscovitine (▲) with concentrations that ranged between 0.01 and 100 \(\mu\)M. Data (mean ± SD) represent measurements from 3-5 individual patient samples.

**Figure 4. SNS-032 reduced the expression of anti-apoptotic proteins.** The total RNA and protein of CLL cells from the same set of 6 patients in Figure 1A were isolated after 6 (■) and 24 hr (●) of incubation with 0.1, 0.3 and 1 \(\mu\)M SNS-032. (A) The mRNA levels of Mcl-1, XIAP, and Bcl-2 were measured by real-time RT-PCR, each performed in duplicate, and compared with time-matched controls. (B) A representative immunoblot from patient 4. (C) Quantitations of immunoblots of Mcl-1, XIAP and Bcl-2 from the same samples described above. Levels of Mcl-1, XIAP and Bcl-2 were normalized to Actin and expressed as percentage of time-matched controls. (D) SNS-032 induced Mcl-1 reduction is independent of caspase activity. CLL cells were pre-incubated with pan-caspase inhibitor ZVAD-FMK (100 \(\mu\)M) or proteosome inhibitor MG-132 (10 \(\mu\)M) for 1 hr before incubating with 0.3 \(\mu\)M SNS-032 for 8 hr. PARP cleavage and Mcl-1 protein levels were visualized by immunoblotting.
**Figure 5. SNS-032 induced loss of mitochondrial membrane potential.**  CLL cells were incubated with 0.3 μM SNS-032 for 6 and 24 hr. Mitochondrial membrane potential and viability were measured by TMRM and annexin V-FITC double staining.

**Figure 6. Recovery of RNA synthesis and re-synthesis of anti-apoptotic proteins when the CLL cells were washed into fresh media without SNS-032.**  (A) Time dependence of SNS-032 induced cell death.  CLL cells were incubated with 0.3 μM SNS-032, and cell death was measured every two hr by annexin V/PI staining (●) comparing to time matched controls (○). Data represent mean ± SD of four CLL patient samples.  (B) CLL cells were incubated with SNS-032 for 6 hr, and apoptosis was measured by annexin V /PI staining (white bar).  One portion of the cells was washed and then incubated in fresh medium without SNS-032 till 24 hr (grey bar), and cell death was compared to cells that were continuously exposed to SNS-032 for 24 hr (solid bar). Data represent mean ± SD of five CLL patient samples.  (C) Recovery of RNA Pol II phosphorylation and anti-apoptotic proteins when SNS-032 was washed out.  After incubating with 0.3 μM SNS-032 for 6 hrs, the cells were washed into fresh media and collected for analysis every 3 hrs.  The phosphorylation status of RNA Pol II at Ser2 and Ser5, and protein levels of Mcl-1 and XIAP were measured by immunoblotting, and compared between time matched controls (ctrl), cells exposed to SNS-032 continuously (SNS) and cells washed at 6 hr and placed in drug-free media (wash). *: non-specific band.  (D) Recovery of RNA synthesis after washing out SNS-032.  [³H]uridine incorporation was presented as percentage of time matched controls (◼).  (●): cells were washed at 6 hr into drug free media; (▲): cells were
incubated with SNS-032 continuously. Data represents mean ± SD of three experiments each done in triplicate.
