KEY POINTS

- Adult patients with early T-cell precursor acute lymphoblastic leukemia/lymphoma (ETP-ALL/LBL) have poor long-term outcomes.

- Novel therapies are urgently needed for adult patients with ETP-ALL/LBL.
ABSTRACT

Early T-cell precursor (ETP) acute lymphoblastic leukemia/lymphoma (ALL/LBL) is a recently recognized high-risk T-ALL/LBL subgroup. The optimal therapeutic approaches to adult patients with ETP-ALL/LBL are poorly characterized. In this study, we compared the outcomes of adults with ETP-ALL/LBL who received treatment on frontline regimens to those of patients with other T-ALL/LBL immunophenotypic subtypes. Patients with newly-diagnosed T-ALL/LBL who received frontline chemotherapy between the years 2000 and 2014 at The University of Texas MD Anderson Cancer Center (MDACC) were identified and immunophenotypically categorized into early, thymic, and mature per the World Health Organization (WHO) classification using CD1a and sCD3 status. Patients with ETP-ALL/LBL were identified on the basis of the following immunophenotype: CD1a(-), CD8(-), CD5(-/dim), and positivity for one or more stem cell or myeloid antigens. A total of 111 patients with T-ALL/LBL (68% T-ALL; 32% T-LBL) with adequate immunophenotype data were identified. The median age was 30 years (range, 13-79). There was no difference in the outcomes of patients based on the WHO subtypes. A total of 19 patients (17%) had ETP-ALL/LBL. The complete remission rate (CR)/CR with incomplete platelet recovery (CRp) rate in patients with ETP-ALL/LBL was significantly lower than that of non-ETP-ALL/LBL patients (73% vs. 91%; \( p = 0.03 \)). The median overall survival for patients with ETP-ALL/LBL was 20 months vs. not reached for the non-ETP-ALL/LBL patients (\( p = 0.008 \)). ETP-ALL/LBL represents a high-risk
disease subtype of adult ALL. Novel treatment strategies are needed to improve treatment outcomes in this T-ALL/LBL subset.

INTRODUCTION

T lymphoblastic leukemia/lymphoma (referred as T-ALL/LBL in this manuscript) is a malignant neoplasm of immature T-cells. Immunophenotypic subtypes of T-ALL/LBL that correspond to T-cell maturation stages have been recognized.1-4 Recently, a subtype of T-ALL/LBL derived from thymic cells at the early T-cell precursor (ETP) differentiation stage has been recognized.5,6 Early T-cell precursors are recent immigrants from the bone marrow to the thymus, derived from hematopoietic stem cells, which retain a certain level of multilineage pluripotency.7,8 By gene expression profiling (GEP), ETP cells share similarities with hematopoietic stem cells and myeloid progenitor cells.5 The definition of ETP-ALL/LBL is based on the immunophenotype of the leukemic cells, which are typically CD1a(-), CD8(-), CD5(-/dim), and positive for one or more stem cell or myeloid antigens.5 In the WHO classification, ETP-ALL/LBL falls within the ‘early’ T-ALL/LBL category. ETP ALL has been reported in 11-12% of childhood T-ALL/LBL5,9, and in 7.4% of adult T-ALL/LBL9. ETP-ALL/LBL is also characterized by a distinct molecular profile with a lower incidence of NOTCH1 mutations and frequent presence of FLT3 and DNMT3A mutations.6,10-12 Importantly, ETP-ALL/LBL is associated with a significantly worse outcome in children and young adults compared to other T-ALL/LBL subtypes.5,13
Combination chemotherapy has been the cornerstone of T-ALL/LBL treatment. Yet, despite an overall complete response (CR) rate of 90-95%, approximately one-third of patients experience disease relapse, and the 5-year overall survival (OS) rate for adults is around 50-55%. These outcomes highlight the need for alternate therapeutic approaches, ideally based on a prognostication strategy that identifies T-ALL/LBL patients at a high risk for relapse.

The aim of this study is to characterize the clinical features of patients with ETP-ALL/LBL seen at our institution and treated on frontline regimens for T-ALL/LBL, and to compare their outcomes to those with other T-ALL/LBL subtypes.

**METHODS**

**Study Group**

Patients with newly-diagnosed T-ALL/LBL who received frontline chemotherapy between the years 2000 and 2014 at The University of Texas MD Anderson Cancer Center (MDACC) were identified. All patients fulfilled diagnostic criteria of T-ALL/LBL according to the WHO classification. The diagnosis of T-ALL/LBL was based on the identification of a neoplastic proliferation of small to medium-sized blasts in an extramedullary mass, peripheral blood (PB) and/or bone marrow (BM). A cutoff of <20% BM blasts was used to define lymphoblastic lymphoma (LBL). Blasts expressed T-cell lineage markers (CD2, cytoplasmic CD3, surface CD3, CD4, CD5, CD7 and/or CD8) as well as markers of precursor T lymphoblasts (CD1a, CD34, CD99 and/or terminal deoxynucleotidyl...
transferase (TdT)). The immunophenotype was assessed by review of multiparameter flow cytometry (MFC) analysis scatter plots and/or quantitative immunophenotyping data on record. The immunophenotype was preferentially based on pretreatment PB, BM or extramedullary tumor material. In a minor subset of patients (n=4), the immunophenotype was based in part on immunohistochemical (IHC) analysis. All the latter cases were lymphoblastic lymphoma (LBL) with a thymic immunophenotype; none were ETP-ALL/LBL. Minimum requirements for immunophenotypic markers included the following: CD1a, CD2, CD3 (surface vs. cytoplasmic), CD4, CD5, CD7, CD8, CD13, CD19, CD33, CD34, CD117, HLA-DR, TdT, and myeloperoxidase. Patients with mixed phenotype acute leukemia such as T/myeloid leukemia as defined in the WHO classification were excluded. Of 127 T-ALL/LBL patients identified, 16 were excluded due to insufficient data for immunophenotypic subtyping. Patients in the study group (n=111) were subtyped based on the expression of CD1a and surface CD3 (sCD3) as early [CD1a(-), sCD3(-)], thymic [CD1a(+), sCD3(-)], or mature [CD1a(-), sCD3(+)] T-ALL/LBL. Patients were also characterized by detailed immunophenotype per WHO criteria (supplemental Table 1). The ETP-ALL/LBL immunophenotype was defined as follows: (1) absent (<5% positive cells) CD1a and CD8 expression, (2) absent or dim (<75% positive cells) CD5 expression, and (3) expression (>25% positive cells) of one or more myeloid (CD11b, CD13, CD33, CD117) or stem-cell (CD34, HLA-DR) markers. Minimal residual disease (MRD) was assessed by MFC with a sensitivity of 0.01% in the remission bone marrow sample for patients who presented with ALL as
described previously\textsuperscript{18}. Briefly, MRD analysis was performed using a panel of markers that included in most cases CD1a, CD2, CD3 (surface and cytoplasmic), CD4, CD5, CD7, CD8, CD10, CD13, CD33, CD34, CD45, CD56, HLA-DR, and TdT assessed on 200,000 aspirated nucleated BM cells.

Patients received frontline treatment with the following chemotherapy regimens: hyper-CVAD alone (\(n=43\)), hyper-CVAD + nelarabine (\(n=44\)) or augmented BFM regimen (\(n=24\)). The details of these chemotherapy regimens were published previously.\textsuperscript{17,19,20} Decision between the 3 regimens was based on a variety of factors: time-period (hyper-CVAD: year 2000 onwards; hyper-CVAD + nelarabine: year 2007 onwards; augmented BFM: year 2006-2012); age (18 years and older for hyper-CVAD based regimens; 40 years and younger for augmented BFM); clinical trial eligibility; insurance coverage of clinical trials; patient or physician preference. CR was defined as disappearance of all clinical and/or radiologic evidence of disease, normal bone marrow differential (\(\leq 5\%\) blasts), no extra-medullary leukemia, neutrophil count \(\geq 1.0 \times 10^9/L\), and platelet count \(\geq 100 \times 10^9/L\). CR with incomplete platelet recovery (CRp) was defined as meeting all criteria for CR except platelets \(< 100 \times 10^9/L\). Response in LBL was assessed by CT imaging studies. Response assessment was performed after induction and every 1-2 months thereafter (until the best response was achieved). Routine allogeneic-stem cell transplantation (allo-SCT) in first clinical remission (CR1) was not recommended. This study was approved by the
MDACC Institutional Review Board and carried out in accordance with the Declaration of Helsinki.

**Statistical analysis**

Fisher’s exact test and Mann-Whitney \( U \) test were used to assess categorical and continuous variables, respectively. The Spearman rank method was used to assess correlations. The Kaplan-Meier method was used to assess OS and event-free survival (EFS) using the log-rank (Mantel-Cox) test. The former was calculated as the time period from the date of diagnosis to the date of last follow-up or death of any cause. The EFS was calculated from the beginning of treatment until an event (relapse, treatment failure, death during induction, or death during complete remission). Patients who received allo-SCT were censored at the time of transplant. Univariate and multivariate analyses were performed to identify potential prognostic factors (age, gender, diagnosis, WBC \( \geq 50.0 \times 10^9/L \), hemoglobin <10 g/dL, platelet <100 \( \times 10^9/L \), LDH \( \geq 600 \) IU/L, CNS involvement at diagnosis, WHO classification (early, thymic, mature), ETP-ALL/LBL, treatment received) associated with OS. For multivariate analyses, we used Cox proportional hazards model for OS. A p-value of <0.05 (two-tailed) was considered statistically significant.

**RESULTS**

A total of 111 patients with T-ALL/LBL who received frontline chemotherapy at MDACC and with adequate immunophenotype data were identified. The median
age was 30 years (range, 13-79) at the time of diagnosis, with 4 patients under
18 years. Twenty-six percent were women. Patient demographics are detailed in
Table 1. Overall, 88% of the patients achieved a CR or CRp. The median follow-
up was 55 months. The 8-year EFS and OS were 48% and 52%, respectively
(Figures 1A and 1B). A total of 32% (35 of the 111 patients) patients presented
as LBL (baseline characteristics of LBL vs. acute lymphoblastic leukemia (ALL)
are detailed in supplemental Table 2). Patients who presented with ALL had an
8-year OS of 44% compared to 70% for LBL (supplemental Figure 1); however,
this was not statistically significant. The presentation for LBL included
mediastinal adenopathy +/- systemic adenopathy (n=22), systemic adenopathy
(n=10), skin involvement (n=1), supraclavicular mass (n=1), and tonsillar mass
(n=1). Seven patients (5 early, 1 thymic, 1 mature) underwent allo-SCT in CR1
for high-risk disease features such as presence of MRD.

When grouped by WHO criteria based on CD1a and sCD3 status, the most
common T-ALL/LBL subtype was thymic (43%), followed by early (includes ETP-
ALL/LBL) (40%) and mature (17%) (demographic details in Table 1). Patients
with thymic subtype were more likely to present with LBL. There was no
difference in the achievement of CR/CRp among patients with early, thymic or
mature T-ALL/LBL subtypes (82%, 94%, and 89%, respectively, p=0.2). There
was no difference in EFS (Figure 2A, p = 0.3) or OS (Figure 2B, p = 0.1) between
WHO subtypes. Comparing early subtype vs. thymic/mature subtypes, the p-
value for EFS and OS were 0.16 and 0.08, respectively. Similarly, there was no
difference in OS when only hyper-CVAD-based regimens (hyper-CVAD alone or in combination with nelarabine) were considered (supplemental Figure 2). Of the 19 patients with mature T-ALL/LBL, only 1 patient underwent allo-SCT in CR1. In this disease subtype, 5-year EFS and OS were 63% and 70%, respectively. Of the 111 patients, only 49 could be subtyped into Pro-T, Pre-T, Cortical T, and Medullary T subtypes, largely due to the discordant expression of differentiation markers that do not conform to this immunophenotypic classification scheme that recapitulates normal T-cell differentiation stages. There was no difference in EFS and OS between these immunophenotypic subtypes (supplemental Figures 3 and 4, respectively).

Overall, 17% (19/111) of the study population had ETP-ALL/LBL. The demographic characteristics of patients with ETP-ALL/LBL are detailed in Table 2. Of the 17 ETP patients where sufficient immunophenotype data was available, 8 patients were categorized as pro-T and 9 patients as pre-T subtype. Patients with ETP-ALL/LBL were less likely to have diploid karyotype, had higher bone marrow blast count (75% vs. 43%, p 0.03), and higher risk of central nervous system (CNS) involvement at the time of diagnosis as compared to non-ETP-ALL/LBL. The CR/CRp rate in patients with ETP-ALL/LBL (68% CR, 5% CRp) was significantly lower than that of non-ETP-ALL/LBL patients (73% vs. 91%; p=0.03). The median EFS for ETP-ALL/LBL patients was 14 months vs. not reached for the non-ETP ALL patients (p = 0.16) (Figure 3A). The median OS for ETP-ALL/LBL patients was 20 months vs. not reached for the non-ETP-ALL/LBL
patients ($p = 0.008$) (Figure 3B). Figure 4 shows OS of WHO ‘early’ patients subcategorized as ETP vs. non-ETP, WHO ‘thymic’ and WHO ‘mature’. Within the WHO ‘early’, ETP-ALL/LBL remained a poor subgroup. The baseline characteristics of ETP patients compared to ‘early’ non-ETP patients is detailed in supplemental Table 3. Patients with ETP presenting as ALL ($n=15$) had significantly worse OS compared to non-ETP patients with ALL presentation ($n=61$) (Figure 5, $p=0.037$). There was no difference in EFS (supplemental Figure 5 $p=0.337$). For patients presenting as LBL, there was no difference in outcomes of ETP ($n=4$) vs. non-ETP ($n=31$), likely due to small numbers (supplemental Figures 6 and 7). Three patients with ETP-ALL/LBL underwent allo-SCT in first remission (one patient is in ongoing CR for 6+ years; one patient relapsed after 3 years, and has achieved CR2 with plans for second allo-SCT; one patient relapsed after 1 year, and is receiving salvage therapy).

The prognostic significance of ETP-ALL/LBL was maintained when only hyper-CVAD based chemotherapy regimens were considered (supplemental Figure 8). As it was difficult to assess for MRD in patients presenting with LBL due to lack of remission tumor biopsy, MRD analysis was restricted to patients presenting with ALL. A total of 54 patients who presented with ALL had MRD data available at the time of remission. There was no difference in the MRD rate in patients with ETP-ALL (7/10 [70%]) vs. non-ETP-ALL (27/44 [61%], $p=0.61$). MRD negativity didn’t influence the outcomes for patients with ETP-ALL; however, the patient numbers were small. By univariate analysis, the following variables were
significant for survival: age, WBC count (<50 vs. ≥50 x10^9/L), platelet count (<100 vs. ≥100 x10^9/L), LDH (<600 vs. ≥600 IU/L) and ETP-ALL/LBL (Table 3). By multivariate analysis, only age (HR: 2.862; 95%CI: 1.140-7.183; p=0.025) and ETP-ALL/LBL (HR: 2.275; 95%CI: 1.117-4.631; p=0.023) were significant (Table 3).

A subset of patients with early T-ALL/LBL had an immunophenotype that resembled that of ETP-ALL/LBL except for having ≥75% CD5 expression (ETP+CD5).9 The OS of patients with ETP+CD5 (n=19) was similar to that of non-ETP-ALL/LBL patients and differed from that of ETP-ALL/LBL patients (p=0.059) (supplemental Figure 9).

**DISCUSSION**

We report here one of the largest series of newly-diagnosed adult patients with ETP-ALL/LBL with long-term clinical outcomes. All patients received induction chemotherapy at our institution with either hyper-CVAD chemotherapy or augmented BFM chemotherapy.17,19,20 Our findings show (1) significantly poorer long-term outcomes for ETP-ALL/LBL patients compared to non-ETP-ALL/LBL patients; (2) lack of the prognostic significance of the WHO-defined immunophenotypic T-ALL/LBL categories; and, (3) favorable long-term outcomes of mature T-ALL/LBL without allo-SCT.
Immunophenotypic subtyping of T-ALL/LBL is commonly used to stratify patients. The German group (GMALL) reported subtype-oriented treatment results in a large group of 744 patients with T-ALL/LBL (ages 15 to 55 years) who were treated on the sequential GMALL clinical trials (05/93, 06/99, 07/03). In their series, thymic was the most common subtype (56%), followed by early (23%), and mature (21%). In the GIMEMA ALL study reported by Vitale et al., early T-ALL/LBL was the most common subtype (51%), followed by thymic (39%), and mature (10%). In the present study, thymic (43%) is the most common T-ALL/LBL subtype, followed by early (40%), and mature (17%). The prognostic impact of this immunophenotypic classification has been limited. Marks et al reported outcomes of 356 adult patients with T-ALL treated on the UKALLXII/ECOG 2993 study. With the exception of CD1a expression, which was associated with a more favorable 5-year OS (64% vs. 39%; p = 0.01), none of the other WHO-defined immunophenotypic categories affected clinical outcomes. They also noted that expression of myeloid markers such as CD13 was associated with a worse 5-year OS (35% vs. 61%; p < 0.001). In retrospect, it could be postulated that these findings reflect the impact of admixed ETP-ALL/LBL cases. In the present report of newly-diagnosed patients with T-ALL/LBL, we were unable to confirm the prognostic significance of any of the WHO-defined T-ALL/LBL subtypes.

The GMALL group has reported a beneficial effect of allo-SCT for patients with early and mature T immunophenotype. The beneficial effect of the transplant
was especially pronounced in patients with mature T-ALL/LBL where the 10-year OS was only 25% without an allo-SCT vs. 59% for those who had an allo-SCT. In the present report, only 7 patients underwent allo-SCT in CR1 as routine use of allo-SCT in CR1 was not recommended. Of the 19 patients with mature T-ALL/LBL, only 1 patient underwent allo-SCT in CR1. Despite this, we report a 5-year EFS and OS of 63% and 70%, respectively in mature T-ALL/LBL subtype. Therefore, we believe that allo-SCT in CR1 should not be considered standard for patients with mature T-ALL/LBL.

A total of 32% patients presented as LBL with the most common presentation being mediastinal mass. Patients presenting with LBL were more likely to have diploid karyotype compared to patients with ALL. Patients who presented with LBL appeared to have an improved survival compared to those presenting with ALL with an 8-year OS of 70% vs. 44%, respectively; however, this was not statistically significant. This is consistent with other published series\textsuperscript{22,23}

ETP-ALL/LBL represents a disease subtype whereby blasts are derived from the earliest T-cell precursors in the thymus and have multilineage pluripotency.\textsuperscript{5,7,8} In children, ETP-ALL/LBL is associated with older age and a lower presenting white blood cell count than seen in the non-ETP-ALL/LBL patients.\textsuperscript{5,9,24,25} In our series, there was no major difference in the baseline characteristics of ETP-ALL/LBL patients compared to non-ETP-ALL/LBL patients with the exception of the former having a higher likelihood of having clonal cytogenetic abnormalities, elevated
BM blast counts, and a higher risk of CNS involvement at presentation. Children with ETP-ALL/LBL are less likely to be morphological early responders and are more likely to have minimal residual disease at the end of induction therapy. In the original report from the St. Jude Children’s Research Hospital group, patients with ETP-ALL/LBL had a significantly worse 10-year OS (19% vs. 84%, p <0.0001) and 10-year EFS (22% vs. 69%, p <0.0001) compared to other patients with T-ALL/LBL. The 10-year cumulative incidence of relapse (CIR) was also significantly higher in patients with ETP-ALL/LBL (72% vs. 10%, p <0.0001). However, the Children’s Oncology Group (COG) recently reported that despite a higher likelihood of a positive MRD assessment at the end of induction in patients with ETP-ALL/LBL, their long term outcomes were similar to the outcomes of the non-ETP patients, with 5-year EFS and OS of 87% and 93%, respectively. This was likely due to treatment intensification of MRD-positive patients. Patrick et al. reported similar data for the UKALL2003 trial where children with ETP-ALL/LBL had relatively favorable long-term outcomes despite having high rates of rates of MRD at the end of induction. The reason for relatively favorable long-term outcomes of ETP-ALL/LBL patients in the COG and UKALL2003 study is not clear, but it is likely that treatment intensification for MRD-positive patients may have abrogated the negative prognostic impact of ETP-ALL/LBL. In our series, we report significantly poor outcomes in patients with ETP-ALL/LBL with a lower CR rate and a lower 5-year OS. The negative prognostic impact of ETP-ALL/LBL persisted when only hyper-CVAD-treated patients were considered. In addition, 9 of the 19 patients with ETP-ALL/LBL
were treated on the hyper-CVAD + nelarabine clinical trial.\textsuperscript{17} The addition of nelarabine does not appear to have improved the outcomes of ETP-ALL/LBL in this small number of patients (supplemental Figures 10 and 11). Only limited data is available from other studies of adult patients with ETP-ALL/LBL.\textsuperscript{10,26} Vlierberghe et al stratified adult patients with T-ALL/LBL by GEP as opposed to the surface immunophenotype into early immature T-ALL/LBL and cortical/mature T-ALL/LBL.\textsuperscript{26} The early immature group had a lower OS compared with that seen in the cortical/mature group (5-year OS 34\% vs. 62\%, respectively, \( p = 0.01 \)). Neumann et al reported outcomes of WHO ‘early’ T-ALL/LBL with a 5-year survival of 35-40\%, and further categorization into ETP vs. non-ETP did not influence clinical outcomes.\textsuperscript{10} In contrast, we report that even within the WHO ‘early’ group, ETP-ALL/LBL retained prognostic significance. The prognostic impact of ETP subtype was maintained when only patients presenting with ALL were considered (Figure 5); for patients presenting as LBL, there was no difference in outcomes of ETP vs. non-ETP, likely due to small number of patients.

Several recent studies have characterized the molecular and genetic makeup of ETP-ALL/LBL.\textsuperscript{6,11,12,26} Several mutations that are common in acute myeloid leukemia such as \textit{FLT3} internal tandem duplication and \textit{IDH1/IDH2} have been described in patients with ETP-ALL/LBL.\textsuperscript{26} This is not unexpected given that ETP cells are early HSC derivatives that retain myeloid potential. These mutations are clinically actionable and thereby can provide a treatment strategy for a subset of
patients with ETP-ALL/LBL. Chonghaile et al recently reported that ETP-ALL/LBL is dependent on Bcl2 and therefore Bcl2 antagonists such as ABT-199 may offer a potential therapeutic strategy.\textsuperscript{27,28} Maude et al reported aberrant activation of the JAK/STAT pathway in ETP-ALL/LBL and showed \textit{in vivo} efficacy of the Jak2 inhibitor ruxolitinib.\textsuperscript{29}

In summary, ETP-ALL/LBL represents a high-risk disease subtype of adult ALL. Novel treatment strategies are needed to improve treatment outcomes.

Diagnosis = ALL vs. LBL; Treatment received = Hyper-CVAD, Hyper-CVAD + Nelarabine, Augmented BFM

Abbreviations: ALL=acute lymphoblastic leukemia; LBL=lymphoblastic lymphoma; LDH=lactate dehydrogenase;
CNS=central nervous system; Dx=diagnosis; WHO= World Health Organization; ETP=early T cell precursor
FIGURE LEGENDS

Figure 1. Survival for the entire study population. (A) Event-free survival and (B) overall survival for the entire study population of patients with T-ALL/LBL (N=111)

Figure 2. Survival for the entire study population categorized by immunophenotype per WHO classification. (A) Event-free survival and (B) overall survival of patients with T-ALL/LBL (N=111) categorized as Early, Thymic and Mature per WHO Classification

Figure 3. Survival for the entire study population categorized as ETP vs. non-ETP. (A) Event-free survival and (B) overall survival of patients with ETP ALL (N=19) compared to non-ETP ALL (N=92)

Figure 4. Survival for the entire study population categorized as ETP and WHO classification. Overall survival of patients with WHO ‘early’ subcategorized as ETP vs. non-ETP, WHO ‘thymic’, and WHO ‘mature’ (N=111)

Figure 5. Survival for the patients presenting as ALL categorized as ETP vs. non-ETP. Overall survival of ETP subtype (presenting as ALL, n=15) vs. non-ETP subtype (presenting as ALL, n=61)
Figure 1

B
Figure 2

A

B

Total Events Median
- Early: 44, 23, 1.6 Yr
- Thymic: 48, 20, NR
- Mature: 19, 8, NR

p = 0.3

Total Died Median
- Early: 44, 20, 2.8 Yr
- Thymic: 48, 17, NR
- Mature: 19, 6, NR

p = 0.1
Figure 3

**A**

Event-Free Survival Probability

- ETP: 19, 11, 1.2 Yr
- Non-ETP: 92, 40, NR
- p = 0.17

**B**

Survival Probability

- ETP: 19, 12, 1.7 Yr
- Non-ETP: 92, 31, NR
- p = 0.008
Figure 4

The figure shows a Kaplan-Meier survival analysis with the following categories and statistics:

- **WHO Early (ETP)**: 19 deaths, median survival 12 months, with a p-value of 0.022.
- **WHO Early (non-ETP)**: 25 deaths, median survival 8 months, not reported (NR).
- **WHO Thymic**: 48 deaths, median survival 17 months, not reported (NR).
- **WHO Mature**: 19 deaths, median survival 6 months, not reported (NR).

The x-axis represents time in years, ranging from 0 to 16, while the y-axis represents survival probability, ranging from 0.0 to 1.0.
